Electricity (period.)

SUPPLEMENT TO "THE ELECTRICIAN," NOVEMBER 9, 1888.

THE ELECTRICIAN:

ASTOR LIBRARY FEB 28 1893 NEW YORK

A WEEKLY ILLUSTRATED JOURNAL OF

-14542-

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXI.

FROM MAY 11, 1888, TO NOVEMBER 2, 1888.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1888.

INDEX TO "THE ELECTRICIAN."

VOL. XXI.

Leading Articles and Editorial Notes.

(In this Section LEADING ARTICLES are shown in Capitals.)

Alternate-Current Electrolysis, 258, 295, 719.
Alternate-Current, Rotation by means of, 810.
Anonymous Correspondence, 34.
Arc Lighting, Unremunerative, 488.
Atlantic Cable Company Negotiations, 293.
ATLANTIC CABLE RATES, THE, 408.
AUSTRALASIAN CABLES, THE, 760.
Australasian Cables, Breakdown of the, 257, 487.
Austria, Electric Lighting Rules in, 258.
Ayrton's, Prof., Lecture at Bath, 548.
Barnet, 295, 618.
Bath, 360.
Bismuth in the Magnetic Field, 458.
Bradford, The Electric Light at, 134.
Bradford Municipal Station, The, 810.
BRITISH ASSOCIATION AT BATH, THE: 1864 AND 1888, 528.
British Association at Bath, The, 579.
British Association of Medical Electricians, The, 198.
British Electric Light Company, The, 517.
Brown's, Mr. Harold, Experiments, 488.
Cables in Time of War, 258.
CHESBOROUGH PATENT, THE, 374.
Chelsea Electricity Supply Company, The, 397, 809.
City and Southwark Subway Company, The, 458.
City, The, Electric Lighting of, 655.
Coast Telegraphy, 102, 458.
Company-mongering Scandals, 809.
Continuous-Current Transformation, 101.
Continuous *versus* Alternating Current Discussion, The, 33, 398.
Counsel, The Technical Knowledge of, 293.
Death by Electricity, 2, 167, 258, 361, 488, 580, 690, 691.
Delany's Cable Key, 398.
Delany's Lineman Protector, 198
Deptford Central Station, The, 779.
Diamagnetism, Experiments in, by M. Blondlot, 165.
DISCUSSION ON LIGHTNING CONDUCTORS AT THE BRITISH ASSOCIATION, THE, 632.
Duplex Working, Mr. W. F. Melhuish's Improvements in, 689.
Dynamo without Commutator or Brushes, A, 617.
EARLY HISTORY, THE, OF THE ALTERNATE CURRENT TRANSFORMER, 272.
Edison Patents in the United States, The, 197.
Edison *versus* the U. S. Electric Lighting Company, 320.
Edison's Business Agents, 329.
Electric Balances, Sir William Thomson's, 1.
Electric Current, The, A New Method of Producing, 750.
ELECTRIC FIRE-ALARMS, 80.
Electrical Inspectors, 428.
ELECTRICAL INTERESTS IN AMERICA, 144.
ELECTRIC LIGHTING ACT AMENDMENT BILL, THE, 203.
Electric Motor, The, on Ship-board, 690.
Electric Traction, 101, 197, 228, 361, 397, 427, 548, 690, 719, 780.
ELECTRICAL TRADES AND THE LONDON CHAMBER OF COMMERCE, 341, 822.
Electrical Section, An, of the British Association, 487.
Electricity, Modern Views of, 547, 749.
Faraday, An Analogy of, 33.
Ferraris Alternate-Current Motor, The, 70.
Finsbury Technical College, 656.
FIRE RISKS OF ELECTRIC LIGHTING, THE, 46.
FitzGerald's, Prof., Address, 548.
Forbes', Prof., Coulomb Meter, 2
French Atlantic Cable Company, The, 166.
GAULARD AND GIBBS *versus* FERRANTI, 308.
Gaulard-Gibbs Patent, The, 257, 293, 517.
Globular Discharge Experiments, 457.
Gravesend, Series System of Electric Traction at, 690.
GROWTH OF ELECTRICAL INDUSTRIES, THE, 560.
Guillemin, Prof., Remarkable Paper by, 294.
Houses of Parliament, The Electric Lighting of, 293.
Incandescent Lamp Company Amalgamation, 134.
INCANDESCENT LAMP LITIGATION, 340.
Incandescent Lamp Trade, The, 809.
Incandescent Lamps for Night Fishing, 166, 750.
Incandescent Lamps, The Maximum Efficiency of, 227.
Influence Machines, Prof. S. P. Thompson on, 133.
Inner Circle, The, Electric Tract on on, 228, 361, 397, 427, 548.
Insurance Surveyors, Electrical Education of, 618.
Inter-Urban Telephone Extensions, 429.
James, Sir Henry, Speech of, 293.
Kennelly's, Mr., Experiments on Dogs, 691.
Leamington, 69, 102, 330, 719.
Lightning Conductors, Observational, 410.
Lightning, Duration of, M. Trouvelot on, 457.
Lloyd's Signal Station Bill, 458.
LOCAL AUTHORITIES AND ELECTRIC LIGHTING, 468.
Lodge and Hughes Correspondence, The, 294.
London Chamber of Commerce, The, 779.
London Electric Supply Company's, The, Works at Deptford, 779.
London Street Tramways Company, The, 427.
Magnetic Nomenclature, 1, 34.
Mann Lectures, The, 293.
Manufacture of Light, The, 520.
Maxim-Weston Company, The, 198, 331, 656, 689, 719.
Metropolitan Electric Supply Company, The, 359, 397.
Medical Electricity, The Institute of 810.
Mill Lighting, Fine Specimen of, 780.
Mixed Systems of Distribution, 102.
Mordey Alternator, The, 69.
MUNICIPALITIES, THE, AND ELECTRICAL ENGINEERING, 112.
National Electric Light Association, The, Meeting of, 617.
National Telephone Exchange Association, The, Meeting of, 655.
Nickel, Impure, Magnetic Properties of, 517.
Night Fishing, Incandescent Lamps for, 166, 750.
North Metropolitan Line, The, Electric Traction on, 719.
Ohm, The, A Redetermination of, 227,
Paris, Electric Lighting Regulations in, 70.
Paris Exhibition, The, and English Electrical Firms, 359.
Patent Agents, The Registration of, 690.
Patent Laws, English and Foreign, 329.
Patent Litigation in the States, 458, 517.
PATENTS BILL, THE NEW, 790.
PHYSICS IN PUBLIC SCHOOLS, 493.
Pilsen-Joel Company, The, 229, 330, 488.
Planté's, M. Gaston, Experiments, 398.
Postmaster-General's Annual Report, The, 548.
Postal Telegraph Testing Instructions, The, 294.
Postal Telegraphs, The Finances of, 330.
POSTMASTER-GENERAL'S REPORT, THE, 594.
PRACTICE *versus* THEORY, 730.
Practice *versus* Theory, 749.
Preece, Mr., and Electrical Nomenclature, 655.
Rechniewski Motor, The, 487.
Royal Society *Conversaziones*, 2, 134.
SCIENCE IN COURTS OF JUSTICE, 438.
Sewage Process, Mr. Webster's, 549.
Sheffield Telephone Exchange, The, 166.
Société Internationale des Electriciens, The, 227.
SOCIETY OF ARTS MOTOR TRIALS, THE, 700.
Society of Telegraph Engineers, The "Ten Minutes Rule at the, 70.
Solomon's Temple, Electrical Protection of 720.
Space of Four Dimensions, 617.
Submarine Telegraph Company, The, 398.
Suburban Electric Supply Company, The, 780.
Sugar Refining by Electricity, 359, 580, 656.
Tavener's Coulomb Meter, 70.
Technical Education, 193, 294, 427, 579, 720.
TECHNICAL EDUCATION FOR SOUTH LONDON, 178.
Technical Instruction Bill, The New, 198, 294.
Telautograph, The, 429, 487.
Telegraphist, The, 35.
TELEPHONE AMALGAMATION, 12.
Telephone Conductors, Size of, 488.
Telephone Systems, The Metropolitan and the Provincial, 518.
TELEPHONIC COMMUNICATION, 238.
Telephonic Communication with Ships, 165, 198.
Thunderstorm, Ballooning in a, 518.
Tramways Act of 1870, The, and the Electrical Interests, 719.
Tudor Accumulator, The, 165.
Underground Electric Railway in Paris, An, 361.
UNDERGROUND WIRES IN AMERICA, 668.
Unflashed Filaments, 517.
United Telephone Company, The, 294, 457, 655.
Vacuum, Conductivity of a, 102.
Van der Weyde, Dr. on High-Tension Currents, 580.
Van der Weyde, Dr., and Mr. Harold Brown, 690.
Van Rysselberghe System, The, 33.
Watt Dynamo, The, 71.
Webster's Sewage Process, 549.
Weymersch Battery, The, 197.
Woodhouse and Rawson (Limited), 34.

Foreign Correspondence.

AMERICAN NOTES.

Accumulator System of Electric Traction, The, 94.
Alloys, Remarkable, 448.
Alternating and Continuous Currents, Comparative Danger of, 319, 415, 478.
American Institute of Electrical Engineers, The, 125.
Baltimore, Electric Tramways in, 25.
Baxter Motor, The, 609, 741.
Bulletin Board, Delany's Electrical, 447.
Cable, Rates, The, 416.
C. and C. Motor, The, 609.
Central Lighting Stations Struck by Lightning, 509.
Chicago, Proposed Electric Underground Railway for, 319.
Cincinnati Centennial Exhibition, The, Electrical Display at, 767.
Craig Machine Telegraph, The, 447, 539, 710.
Daft Factory in New York, The, 94.
Death by the Electric Current, 155.
Delany's Electrical Bulletin Board, 447.
Delany's New Cable Key, 218.
Dynamos for Telegraph Purposes, 510, 799
Edison Association, The Meeting of, 509.
Edison's New Laboratory, 349.
Electric Light and Power Statistics, 681.
Electric Light Company Consolidation, 349.
Electric Light Switch-board, A Big, 828.
Electric Motors in the States, 60, 186.
Electric Railway Activity, 478, 609, 683, 711, 741
Electric Railway, An Ingenious Form of, 767.
Electrical Journalism, Development of, 711.
Electricity and Politics, 829.
Elevated Railways, 218.
English Patent Decisions, The, 417.
Enos System of Electric Traction, The, 154.
Equitable Insurance Building, The, Lighting of, 478
Forbes Meter, A New, 540.
Gardner System of Controlling Clocks, The, 385.
Gaulard and Gibbs Patent Decision, The, 538.
Geyer Galvanometer, The, 186.
Gedney's Channel, The Electric Lighting of, 828.
Gramophone, The, 125.
Graphophone, The, 285, 349, 384, 416, 448.
Howell Voltmeter, A New, 539.
Incandescent Lamps in Explosive Gases, 94.
Julien Electric Traction Company's Station, The, 828.
Keely Motor, The, 711.
Leclanché Cells for Telephone Purposes, 682.
Lugo Motor, The, 385.
"Magnet," The, 284.
Magnetic Club, The Formation of the, 61.
Men-of-War, Electric Motors on, 249, 710.
Military Telegraph Companies, The, at Chicago, 610.
Mine Hoist, An Electric, 154.
Motor Service, Mr. Lufkin on, 682.
Municipal Lighting, Mr F. H. Whipple on, 320.
Municipal Rapid Transit Problem, The, Solution of, 285, 800.
National Electric Light Association, The, Meeting of, 681.
National Telephone Exchange Association, The, Meeting of, 682.
New York Telephone Exchange, The, 510, 682.
New York, The, Electrical Subways, 25, 416.
O'Keenan Battery, The, 349.

Digitized by Google

Foreign Correspondence (*continued*).

Overhead Wire Agitation in New York, The, 60, 186, 249, 284, 320, 348, 384, 539, 740, 767.
Patent Reform, 186, 767.
Petroleum Fuel, The Use of, 681.
Phonograph, The, 125, 218, 285, 349, 416, 448, 683.
Quezaltenango, Electrical Plant for, 610.
Sawyer-Man Electric Company, 154.
Series *v.* Parallel System of Electric Traction, The, 218.
Shallenberger Meter, The, 572.
Ship Electric Lighting Plant, 710.
Shippey Bros., Circular by, 572.
Sibley, Mr. Hiram, Death of, 385.
Sprague System, The, 218, 285, 448, 473, 683, 711, 741, 800.
St. Louis Telephone Company, The, and the Local Government, 249.
Static Electricity, Prof. A. M. Meyer on, 60.
Street Lighting, Incandescent Lamps for, 348.
Telautograph, The, 479.
Telegraph Operators, Agitation among, 384.
Telephone Litigation, 93, 154, 219, 448, 709.
Telephone Transmitters, Testing Apparatus for, 94.
Telephonic Conversation, Recording, 539.
Telephony *v.* Telegraphy, 185.
Tesla Motor Patents, The, Purchase of, 683.
Thomson Electric Welding Company, The, 218, 348.
Thomson-Houston Regulator Patent, The, 538.
Thomson's, Prof. Elihu, Coulomb Meter, 26, 249.
Underground, Electric Traction on the, 385.
Waterhouse Constant Current Dynamo, The, 740.
Water-Power, The Electrical Utilisation of, 766, 799.
Western Union Telegraph Company, The, 683, 709.
Westinghouse and Sawyer-Man Companies, The, 827.
Wind-Power and Electricity, 93.

BARCELONA NOTES.

Barcelona Exhibition, The, 501.

BERLIN NOTES.

Central Station Lighting, Dr. Rühlmann on, 320.
Unter den Linden, The Lighting of, 320.

BRUSSELS NOTES.

Brussels Exhibition, The, 321, 449, 741.
Hoho Continuous Current Transformer, The, 741.
Hoho Multipolar Dynamo, The, 741.

COPENHAGEN NOTES.

Copenhagen Exhibition, The, 285, 611.

PARIS NOTES.

Accumulators, The Employment of, 610.
Cély Accumulator, The, 320.
Central Lighting Station on the Place Ste. Geneviève, 448.
Cruto Lamp Factory, The, 540.
Eiffel Tower, Electric Lift at the, 320.
Electric Fire Alarms in Paris, 448.
Electric Underground Railway, The Proposed, 386.
Electrolysis, A New Application of, 540.
Imprimerie de la Presse, Installation at the, 610.
Khotinsky Company, The, and the Rheims Gas Company, 320.
Lyons Central Station, The, 763.
Maiche Dynamo, The, 219.
Marly Hydraulic Station, The, 769.
Microphonic Apparatus for Military Purposes, A New, 321.
Montpellier, Electric Lighting at, 320.
Municipal Central Lighting Station at the Halles Centrales, 449, 610, 769.
Paris-Marseilles Telephone Line, The, 336.
Paris Municipality, The, and the Electric Light, 219.
Paris Municipality, The, and Electric Traction, 540.

STOCKHOLM NOTES.

"Electran" Company, The, 611.
Gothenburg Electric Company, The, 186.
Stockholm, The Proposed Central Station at, 611.
Sundsvall, Proposed Electric Lighting of, 611.
Vesteros, Electric Lighting of, 611.

VIENNA NOTES.

New Court Theatre, The, Lighting of, 768.
Telephone Progress in Austria, 386.
Siemens and Halske Central Station, The, 540, 763.
Van Rysselberghe System in Austria, The, 386.
Vienna Opera, Lighting of the, 541, 610, 769.

Original Papers, Translations, Extracts, &c.

(In this Section ORIGINAL COMMUNICATIONS are shown with an asterisk.)

Action of Light, The, upon the Static Charge, 739. — BICHAT, E.
*Accumulator Switch-Board and New Metre Bridge, 127.
Alcohol, The Electrolytic Purification of, 789.
*Alternate-Current Electrolysis, 299. — AYRTON, Prof. W. E., and PERRY, Prof. J.
*Alternate Currents, Notes on, 74 141, 334. — FLEMING, Dr. J. A.
Aluminium and Aluminium Alloys, 726.
*Anglo-American Brush Corporation Electrical Engineering Works, 433.
*Asbestos-Packed Cocks, 796.
*Bell's, C. A., Water-Jet Telephone Transmitter and System of Telephonic Communication, 375. — DE TUNZELMANN, G. W.
*Birmingham Tramways, The Cost of Steam, Cable and Horse Traction on the, 796.
Bismuth, The Use of, as a Simple Means of Measuring the Magnetic Field, 471. — LENARD, Dr., & HOWARD, Dr.
*Bradford Central Station, Laying the Foundation Stone of the, 818.
*British Association Meeting at Bath, 564, 622, 660.
*Burglar Alarm Window and Door Contact, 217.
Cance Arc Lamp, The, 680.
*Central Lighting Station, The, of the London Electric Supply Corporation at Deptford, 786, 818.
Central Station Lighting: Curves of Output and Cost, 244. — FRITSCHE, W.
*Charlesworth's Portable Projector Apparatus, 793.
*Conditions of Regulation in Dynamos of Constant Potential, Note on the, 172 (*see also* Letters to the Editor). — ESSON, W. B.
*Conductivity and the Atomic Theory, 381. — GRANVILLE, W. P.
Constant Daniell Cell, On a, for Use as a Standard of Electromotive Force, 445. — BURTON, COSMO I.
*Continuous-Current Transformation, 107. — SELLON, R. P.
*Cox-Walker-Swinton Magneto Bell and Generator, The, 415, 480.
*Crompton and Co.'s, Messrs., Works at Chelmsford, 344.
Damaged Lightning Protector, A, 708.
*Davies', Hubert, Astatic Ammeters and Voltmeters, 447.
*Delany's Improvements in Submarine Cable Telegraphy, 242.
*Delany's Safety Device for Linemen, 209. — CRAWLEY, C. W. S., and NALDER, H.
*Depositing Dynamo, Elwell-Parker's, 188.
Difference of Potential, The, between Certain Metals, &c., in Solutions of Different Strengths, 56.
*Dog Cart, A New Electric, 593.
*Drake and Gorham's Low-Reading Voltmeter, 834.
*Dynamos without Commutators or Brushes, 627. — MARCKER, T
*Edison Improved Phonograph, The, 467.
*Efficiency, The, of the Exchange Telegraph Company's Hydraulic Power Plant when Used for Charging Accumulators, 462. — HIGGINS, F.
Electrical Conductivity, The, of Supersaturated Saline Solutions, 537. — HEIM, C.
*Electrical Power applied to Railways: The Beaumont Gear, 241.
Electrical Traction in Paris, 708.
*Electrical Traction on the Inner Circle, 439, 493, 553. — EVERSHED, E.
*Electro-Dynamic Rotation by Means of Alternating Currents, 86.
*Electro-Magnetic Induction, Notes on, 785, 814. — FLEMING, Dr. J. A.
Experimental Curves of Alternating Currents, 111. — DUNCAN, Dr. L., and Messrs. HUTCHINSON and WILKES.
Experiments on Carbon at High Temperatures and Under Great Pressures, and in Contact with Other Substances, 531. — PARSONS, Hon. C. A.
Experiments, New, on the Electric Arc, 103. — LECHER, Dr.
*Fifty-Unit Dynamo by Paterson and Cooper, 181.
Fifty Kilo.-Watt Goolden-Ravenshaw Dynamo, 121.
*Forms, New, of Secohmmeter and Ayrton and Perry's "Maxwell" Galvanometer, 75.
*Gassner's Dry Battery, 245.
Gérard Arc Lamp, The, 759.
*Glasgow International Exhibition, 239, 464.
*Graser Influence Machine, The, 45.
Gravier Arc Lamp, The, 791.
Gray Telautograph, The, 494
*Harcourt's, Mr. Vernon, New Holophotometer, 412, 474.
*Hertz's Researches on Electrical Oscillations, 587, 625, 663, 696, 725, 757, 788. — DE TUNZELMANN, G. W.
*Hicks Glass-Bead Hydrometer, The, 384.
High and Slow Speed Engines, 337. — POWERS, J. A.
*Improvements in the Telephone System of Glasgow and the West of Scotland, 529, 562, 593, 633. — SINCLAIR, D.
*Influence of Self-Induction on the Rate of Discharge of a Condenser, 39. — LODGE, Dr. O. J.
Insulator, A New, for Delicate Apparatus, 189.
Jaspar Arc Lamp, The, 797.
*Lea's Hand Starter for Gas Engines, 573 (*see also* 612).
*Letters for Learners and Unprofessional Readers, 47, 146, 210, 246, 306, 367, 444, 475, 507, 531, 570, 628, 706, 733, 764, 820. — WILKINSON, H. D.
*Lighting of the Adelphi Theatre, The, 380.
*Lightning Conductors, 815. — LODGE, Dr. O. J.
Lightning Conductors, On the Theory of, 435. — LODGE, Dr. O. J.
*Lippmann Magnetometer, The, 738.
*Macintyre's Wire Joints, 85.
Manufacture of Light, The, 589. — LODGE, Dr. O. J.
*Magnetic Hysteresis, Note on, 585. — FLEMING, Dr. J. A.
Maximum Galvanic Polarisation of Platinum Electrodes in Sulphuric Acid, on the, 185. — FROMME, C.
Mersanne Arc Lamp, The, 739.
*Mica, The Use of, as a Dielectric, 794. — KLEMENCIC, Dr. JGNAZ.
*Mordey Alternator, The, 81.
*Oil Insulator for Shackles, An, 207, 229.
*Oscillations, Electrical, 6 (*see also* Letters to the Editor) — FLEMING, Dr. J. A.
Personal Safety and High-Tension Currents, 373. — DAFT, LEO.
Prix Volta, Report of the Commissioners of the, 496.
*Ransomes, Sims and Jefferies' Engines, 414.
*Rechniewski Alternate-Current Motor, The, 509 (*see also* 573).
*Reduction of Ballistic Observations to Absolute Measure, Notes on the, 604 (*see also* 741). — KENNELLY, A. E.
Regulation of Arc Lamps, The, 446. — HOSPITALIER, M.
*Remarks on Some of Our Telephone Systems, 755 (*see also* 801, 833). — MUNRO, J.
*Reply to Prof. Armstrong's Criticisms regarding the Dissociation Theory of Electrolysis, 554. — ARRHENIUS, SVANTE.
*Rise and Progress of Telephony in the United Kingdom, 41.
*Seel Incandescent Lamp Filament, The, 148.
*Shallenberger Alternating-Current Meter, The, 556.
*Siemens' Coulomb Meter, 183.
*Sketch of the Electrical Papers in Section A at the Recent Bath Meeting of the British Association, 622, 660 (*see also* 712). — LODGE, Dr. O. J.
*Some English Central Lighting Stations, 334, 463.
Specific Resistance of Mercury, The, 538. — GLAZEBROOK, R. T., and FITZPATRICK, T. C.
*Sprague Motors at Richmond, Va., 522. — SNELL, A. T.
*Steam Cylinder Lubricator, The, 513.
*Switches for Connecting and Disconnecting Lamps at Various Points in the Circuit, 20.
*Tainter-Bell Graphophone, The, 533.
*Telephones in the River Plate, 43.
*Tesla Alternating Current Motor, The, 342. — SWINBURNE, J.
*Transmission of Electrical Power Applied to Railways, On the, 108. — COPPER, H.
*"Tudor" Accumulator, Report by Prof. Kohlrausch on the, 180.
*Unipolar Induction, 139, 171, 203, 233, 262, 300, 365 (*see also* Letters to the Editor). — DE TUNZELMANN, G. W.
Use of Electrical Motors, The, on Shipboard, 693 — MURDOCK, Lieut. J. B., U.S.N.
*Voltaic Balance, The, 337. — GORE, Dr. G.
*Voltametric Measurement, The, of Alternating Currents, 724. — KENNELLY, A. E.
*Waring's Lead-Covered Cables, 834.
Waterhouse Method, The, of Dynamo Regulation for Constant Currents, 738.
*Water-Jet Telephone Transmitter, The, 45.
*Wheatstone and Stroh's Submarine Cable Key for Morse Signals, 404.
*Wire-Testing Apparatus, Convenient, 739.
*Woodhouse and Rawson Factories, The, 493.

Letters to the Editor.

Alternate-Current Electrolysis ..... PERRINE, F. A. C., 510.
Anglo-American Telegraph Company's 1869 Cable, The ..... WEAVER, H., 712.
Another Electropathic Fraud ..... "MAGNET," 323.
Arc Light at Eastbourne, The ..... SMITH, WILLOUGHBY, 387.
HAMMOND AND CO., 418.

Ballistic Galvanometer Measurements ..... RIMINGTON, E. C., 741.
Barnet, The Lighting of ..... JOEL (HENRY F.) AND CO., 775.
Bath and the Electric Light ..... MASSINGHAM, H. G., 417.
Beaumont Epicyconoidal Gear, the ..... ARNALL, T., 387, 481.
BEAUMONT, W. W., 450.
Bright, The Late Sir Charles ..... SMITH, WILLOUGHBY, 26.
Clark Standard Cells ..... KENNELLY, A. E., 250 (*see also* 302).
Conditions of Regulation, The, in Dynamos for Constant Potential ..... FRICKER, GUY C., 286, 350.
ESSON, W. B., 321.
"Dark" Flash, The ..... MOSS, JOHN P., 801.
Delany Cable Key, Tests of the ..... DELANY, P. B., 449.
Delany, The, and the Wheatstone-Stroh Cable Keys ..... HIGGINS, F., 322, 480.
DELANY, P. B., 449.

Determining Percentage of Copper in a Cyanide Solution ..... CORRIE, D., 483.

Who is Cheesborough? ..... "IGNORAMUS," 351.
Working Alternators in Parallel ..... BLATHY, O. T., 321.

Scientific Societies, Papers, &c., read before.

Academie des Sciences.

Alternate-Current Electrolysis, 237, 403. — MANEUVRIER, G., and CHAPPIUS, J.
Leyden Jar Discharges and the Influence of the Shape of Conductors, 305. — GUILLEMIN, C. M.

American Institute of Electrical Engineers.

Alternating Current Motor, A New, 173. — TESLA, NICOLA.
Solution of the Municipal Transit Problem, The, 409. — SPRAGUE, F. J.
Some Objections to the Overhead Conductor for Electric Railways, 835. — LEONARD, M. B.
Underground Electrical Conductors in Europe and America, 143. — PLYMPTON, Prof. G. W.

Association of Municipal and Sanitary Engineers and Surveyors.

Sewage Purification by Electrolysis, 558. — WEBSTER, W.

British Association (Manchester Meeting, 1887).

Action of a Magnet on Chemical Action, On an Explanation of the, 534. — ROWLAND, Prof. H. A., and BELL, Prof. L.

British Association (Bath Meeting, 1888).

Apparatus, An, for Determining Temperature by the Variation of Electrical Resistance, 667. — SHAW, W.
Application of Electricity, The, to the Working of a Twenty-Ton Travelling Crane, 665. — ANDERSON, W.
C.-G.-S., On the, and Practical Units of Measurement, 701. — PREECE, W. H.
Comparison of Gassner's Dry Cells with Leclanché's, 703. — CARPENTER, W. LANT.
Electric Light applied to Night Navigation upon the Suez Canal, 669. — SELLON, R. P.
Electric Lighting in America, 640. — FORBES, Prof. G.
Discussion on, 643.
Electric Transmission of Power, The, 598. — AYRTON, Prof. W. E.
Electricity as Applied to Mining, 704. — BRAIN, F.
Electro-Calorimetry, 705 (*see also* 773, 831). — STROUD, W., and GEE, W. W. HALDANE.
Electrometric Determination of "V," 681. — THOMSON, Sir W., AYRTON, Prof. W. E., and PERRY, Prof. J.
Five Applications of Fourier's Law of Diffusion, Illustrated by a Diagram of Curves with Absolute Numerical Values, 736. — THOMSON, Sir W.
Impedance of Conductors to Leyden Jar Discharges, 667 (*see also* 773). — LODGE, Dr. O. J.

British Association (Bath Meeting, 1888)—(*continued*).

Is the Velocity of Light in an Electrolytic Liquid influenced by an Electric Current in the Direction of Propagation? 666. — RAYLEIGH, Lord.
Lightning Conductors (*Discussion on*), 644, 673. — PREECE, W. H., LODGE, Dr. O. J., THOMSON, Sir W., &c
List of Papers dealing with Electricity read at 1888 Meeting, 669.
Mean Intensity of Magnetisation of Soft Iron Bars of Various Lengths in a Uniform Magnetic Field, 823. — TANAKADATE, A.
Measurement of Electricity in a House-to-House Supply, On the, 638. — LOWRIE, W.
Discussion on, 643.
Measurement of Electro-Magnetic Wave Length, 607. — LODGE, Dr. O. J.
Miners' Electric Safety Lamps, 735. — WATTS, N.
Practical Standards for Use in Electrical Measurements, Report of the Committee on, 797.
Presidential Address to Section A, 568. — FITZGERALD, Prof. G. F.
Presidential Address to Section G, 564 (*see also* 620). — PREECE, W. H.
Recent Developments of the Cowles' Aluminium Process, On, 589. — CROMPTON, R. E.
Simple Hypothesis, A, for Electro-Magnetic Induction of Incomplete Circuits, with Consequent Equations of Electric Motion in Fixed Homogeneous or Heterogeneous Solid Matter, 605. — THOMSON, Sir W.
Specific Resistance, The, of Pure Copper, 702. — GLOVER, W. T.
System of Electrical Distribution, On a, 636. — EDMUNDS, H.
Discussion on, 643.
Transference of Electricity, On the, within a Homogeneous Solid Conductor, 762. — THOMSON, Sir W.
Vortex Analogue of Static Electricity, 673. — HICKS, Prof. W. M

Chicago Electrical Club.

Alternating *v.* Continuous Currents, 122. — SLATTERY, M. M. M.

Electrotechnische Verein, Berlin.

Review, A, of the Present Condition of the Theory of the Electrolysis of Solutions, 466, 504. — KOHLRAUSCH, F.

Institution of Mechanical Engineers.

Turbo-Electric Generator, The (*Discussion on*), 476.

National Electric Light Association of America.

Comparative Danger, The, of Alternating *versus* Direct Currents, 592. — VAN DER WEYDE, Dr. P. H.
Disruptive Discharges and their Relations to Underground Cables, 629. — ACHESON, E. G.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 521.—Vol. XXI. FRIDAY, MAY 11, 1888. Price 4d.

NOTES.

Sir William Thomson has added one more to the long series of electric "balance" instruments to which he has devoted much time and labour during the last two years. The new instrument was described in a Paper recently read before the Philosophical Society of Glasgow, of which an abstract will be found in another column. It is designed for the purpose of providing in one apparatus the means of measuring difference of potential, current, and rate of working. Like each of its predecessors in this beautiful series, it is capable of dealing both with direct and alternate currents. It is to be regretted that hitherto comparatively little use has been made of these instruments in the practice of electrical engineering. In their truly marvellous accuracy and extraordinary range no other instruments can pretend to compete with them. We do not, of course, advocate their employment for small isolated plants, but for central station work, particularly with alternating currents, we believe that good results would ensue from the adoption of standard voltmeters of this type. We may also refer to their value as secondary standards for the calibration of the instruments which are placed in the hands of workmen.

One reason which militates against their more general adoption is no doubt the question of cost. But their apparently high price largely arises from the fact that, like all Sir William Thomson's inventions, every smallest detail has been worked out with elaborate care and skill, and with an expenditure of time and labour which finally leaves the instrument as nearly perfect as its materials will ever allow it to be. For instance, we may mention a very elaborate series of experiments upon the behaviour of the band of fine copper wire under prolonged strain, which has been carried out with a view to the elimination of any error which might ultimately arise from this cause. Another thing which has tended to retard their introduction is the idea (which we believe to be a mistaken one) that their use is attended with a good deal of difficulty and delay. It is true the instruments are not direct reading. it is necessary to wait until the beam is in equilibrium; but this disadvantage is easily over-estimated, and of course in practice it is only necessary to see that the pointer makes equal swings on either side of zero. Some few months ago we had the opportunity of receiving instruction in the use of the balance from its distinguished inventor, and with this advantage in our favour we were speedily able to take readings nearly if not quite as rapidly as they can be taken with, say, a Siemens dynamometer, and with incomparably greater accuracy. We feel sure that the time will come when the practical value of these beautiful instruments will be as highly appreciated as their theoretical ingenuity is already.

In the current number of the *Phil. Mag.* Mr. Bosanquet once more does battle on behalf of the phrase "magnetic resistance." Denying that the term "resistance" necessarily implies a linear function, Mr. Bosanquet advocates its general definition as the measure of the ratio of *cause* to *effect*. The term is certainly in ordinary use in this sense, as, for instance, when we speak of the resistance of a body to compression, or of the resistance to the flow of water in pipes. In these and many other cases no one would dream of saying that the term is misapplied, unless it can be shown that the "resistance" varies simply directly as the cause and inversely as the effect. But this is all that the scholastic argument really amounts to, and, notwithstanding the array of eminent names by which it is supported, we should be slow to admit that objections of this character ought to overrule the pressing considerations of practical convenience which demand the use either of this or of some still more appropriate term.

We have, however, the very great satisfaction of announcing that a term has at length been discovered which we are inclined to think renders further controversy needless—a term which, to say the least, is free from any of the objections raised against its predecessor. Several weeks ago we appealed to the Nomenclature Committee appointed by the Council of the Society of Telegraph-Engineers and Electricians for an authoritative decision of the question; but our readers must be prepared for the disappointment of learning that it is not from this source that deliverance has arrived. The new term is proposed by Mr. Oliver Heaviside, to whom we are already indebted for such well-established and invaluable terms as "impedance" and "inductance." As a substitute for "magnetic resistance," Mr. Heaviside suggests the term "Reluctance." It is not a small advantage that we are thereby enabled to drop the prefix "magnetic," which becomes superfluous. The analogue "reluctivity," though not a pretty word, is still quite possible.

Electricity, says the *Lancet*, is not to be depended upon for doing the execution business. Of course it is hard to be told that electricity cannot do everything, but in this relation we are not disposed to resent the imputation. Every elec-

Digitized by Google

trician worthy the name would, it is true, undertake to supply current that would "rupture the veins" (we quote the *Lancet's* words) of the most hardened criminal; but then, happily, only a very few electricians have had any practical experience of its efficacy; and, after all, even the New York "authorities" (whoever they may be) will hardly be inclined to entrust the capital punishments of the Empire City to amateurs, or to let them treat the subject experimentally. Electricity, as the *Lancet* points out, sometimes produces a state of catalepsy closely simulating death, but from which the sufferer sometimes recovers; and it would be a scandal, even in New York, to bury a man alive, or have to slay him over again. Any way, when they come to think of it, the American electricians will not find it "good business" to take credit for supplying the public with an article of such deadly capabilities as a successful response to the "authorities'" invitation would clearly imply.

DR. GORE'S discovery of the effect of chlorine upon the E.M.F. of a voltaic cell, which formed the subject of a Paper read last week before the Royal Society, has enabled him to detect the influence of a chlorine solution differing from pure water by one part in 500,000 millions. This reminds one of the prescription said to have been written by an American homœopathic physician, which ran something like this:—"Take a little aconite (less would be better); put it, with care, into Lake Superior; stir the mixture well. Dose: Half a drop in water."

THE *conversazione* at the Royal Society's rooms on Wednesday evening, although a pronounced success in every sense of the word (which goes, perhaps, without saying), was nevertheless not marked by the display of any striking novelties in electrical experiments or apparatus. Undoubtedly, the most interesting and the most beautiful exhibit of this description was the apparatus employed by Mr. SHELFORD BIDWELL in his researches on the elongation or retraction of the magnetic metals in powerful fields. The latest results of these experiments were recorded in a Paper read before the Royal Society on February 9th, 1888, and printed in *The Electrician* on March 23rd. The marvellous delicacy of the observations is comparable to that of Dr. GORE'S experiment alluded to above—a variation in length amounting to one two-and-a-half-millionth part of an inch being readily perceptible. Mr. STEPNEY RAWSON exhibited a new photometer designed for use with the pentane standard lamp of which our readers will doubtless hear more shortly. Messrs. WOODHOUSE AND RAWSON also showed specimens of the "adamant" carbon which they have recently introduced. This is an extraordinarily hard variety of carbon made by a secret process, and capable of taking a jet-like polish. It is said to give excellent results in the Blake Telephone Transmitter. Some unflashed lamp filaments of this substance were also shown. The Edison-Swan and the Schanschieff miners' lamps, the Bruce signalling balloon, the large Wimshurst machine, and the Robertson Writing Telegraph, although scarcely novelties, contributed to the interest of the Exhibition. We must also not omit to mention Mr. VERNON BOYS' electric "radio-micrometer," which furnishes the most delicate means of appreciating minute variations of temperature yet devised. During the evening Dr. MARCET repeated the simple but striking experiment which he recently showed the Meteorological Society, and which consists in throwing upon a screen a magnified image of an ordinary electric spark; the spark is then seen to possess all the visual characteristics of a lightning flash.

WE have reserved the mention of one exhibit for a separate note. A contemporary journal last week inquired in large type, "Where is Prof. FORBES'S Coulomb meter?" On Wednesday evening the latest and most improved type of this apparatus was to be seen at the rooms of the Royal Society. No important alteration has been made in the design, the improvements having been chiefly confined to matters of detail, tending to make the instrument more suitable for every-day usage. A very simple and highly ingenious device has, however, been adopted, in order to give as it were a final touch to the accuracy of the record. It will easily be understood that after the current has traversed the coil for some time, the whole apparatus has risen slightly in temperature, and the base-plate, from its mass and position, takes longer to cool than the exposed wire. Consequently the vanes tend to rotate for a short time after the current has ceased. In order to check this tendency, a deep ring or collar of india-rubber is placed around the base-plate within the cover. Owing to the higher specific heat and lower radiating power of india rubber compared with the metal, the ring of india-rubber, in spite of its smaller mass, takes as long to part with its heat as the base-plate does. But the convection currents arising from the ring flow upward at the sides of the glass cover and tend to descend in the centre; they thus meet and check the upward current arising from the plate, so that in this way the vanes are speedily brought to rest. The device seems to be very effective. It is, however, an obvious suggestion that a more positive action could be obtained by an electro-magnetic arrangement for locking and unlocking the spindle as the current is turned off or on. We believe, however, that the correction is of little importance in any case.

THE affairs of the Maxim-Weston Company did not receive much further elucidation at the extraordinary general meeting which Mr. HUGH WATT thought fit to call together (as reported last week). The ostensible object of the meeting was "to elect two additional Directors, and to fix the remuneration of the Board." Seeing that the shareholders had only just decided to strengthen the Committee of Investigation by sixteen additional members, it is not surprising that the question of "remuneration" should have been considered scarcely ripe for discussion. The legality of the meeting being challenged, after a protracted and undignified squabble the assembly was dissolved. Since the sixteen additional members of the committee of shareholders have not yet been selected, the announcement that Mr. HUGH WATT intends to prosecute the five original members is doubly interesting, and, whether intentionally so or not, will doubtless tend *pour encourager les autres.*

IT seems to us a little unfair for learned counsel to treat scientific experts in the witness-box as if they were hardened criminals. When a leading scientific man gives evidence he places the facts as they present themselves to him as clearly as he can before the legal but unscientific mind—the anecdote of the three degrees of inaccuracy notwithstanding. The ATTORNEY-GENERAL'S manner in cross-examining Mr. CROOKES in the Edison-Swan action out-Buzfuzed Buzfuz. We felt as if nothing better than drawing and quartering was fit punishment for Mr. CROOKES. This style, though sometimes effective, entirely failed on this occasion to confuse the witness. That, however, is not the point; we hold that it is neither necessary nor proper for counsel to assume a hectoring tone towards men of high standing and reputation while tendering evidence of a purely scientific character.

AS might have been expected, so pernicious an example having once been set has not been long in bearing fruit. From an important (but in point of years, a junior) witness in this case, we have received a communication of a most irreverent character in the shape of a commentary upon the behaviour of his elders in the witness-box. We print a few extracts solely as "shocking examples" to enforce the justice of our complaint:—

"The defendants," says this sprightly critic, "chose their witnesses with some sense of humour. Dr. TIDY appears to be a good witness, but he indulged in a facial accompaniment which made an observer wonder if his identity were really continuous. Prof. SILVANUS THOMPSON had evidently been transplanted from Finsbury College unconsciously. He immediately lectured the judge on the elements of electricity in his very best manner. He was a conjuror, too. He produced a continuous supply of huge wall diagrams from his hind pockets. His lordship seemed an apt pupil, and appears to know more about the case than all the others rolled together. Prof. PERRY must have been called as witness much before his usual hour of rising. All the same, he was really very wide-awake. He objected to cross-examination on moral principles. He complained bitterly that he could not see beforehand where the ATTORNEY GENERAL might lead him. He led him nowhere, however, except into abstruse mathematics. Calculation of an involved kind was his *forte*. On the least provocation he revelled in differential equations. He was full of quantics and graphs. He computed a table of logarithms to nineteen places in the witness-box. His cross-examination was adjourned over night. Next morning he wanted to go through all his calculations again, to show they were right. This the judge gently but firmly declined to permit."

WE print this week a valuable paper on "Electric Oscillations," by Prof. J. A. FLEMING, in which the theory of this somewhat obscure phenomenon is explained in very simple terms. The existence of the phenomenon has long been known—at least, to the mathematical school of electricians—but its practical importance had never been appreciated until Dr. OLIVER LODGE showed what an important part it plays in the lightning flash, and how much that has hitherto seemed inexplicable in the behaviour of lightning conductors is thereby accounted for. Dr. FLEMING extends this explanation in other directions, particularly in regard to the anomalous results of magnetisation by static discharge.

OWING to the extreme pressure upon our space during the last few weeks from the length of the legal intelligence, we have been compelled to omit our Patent Record. We shall shortly take an opportunity of bringing this list up to date.

WITH the present number of *The Electrician* we commence a new volume (the Twenty-First), with which the journal enters upon the eleventh year of its existence. The index of the twentieth volume, which accompanies this issue, has been prepared upon a new plan, which we believe will considerably facilitate its use.

The Electric Lighting Bill.—Lord Thurlow's Bill was read a second time in the House of Commons on Tuesday.

Carthagena.—The Spanish Government is contracting for the construction and working of a telephonic system at Carthagena.

Brussels.—The palace of the Comte de Flandre is now lit by electricity, one Lohmeyer dynamo and a set of Julien accumulators being used.

The British Association.—Prof. Flower has been nominated as President of the British Association for the Newcastle meeting next year.

Personal.—We have to announce the marriage, on the 1st May, at Koenigsberg, of Mr. John Gordon, Electrician of the Swan United Electric Light Company's factory, Cologne, to Gertrud, daughter of the late Sanitaetsrath Doctor Marschall, of Leipzig.

River Plate, Brazil, and United States District Telegraph Company.—Mail advices report that the Argentine Government has approved of a contract with this company for a telegraph and telephone service between Buenos Ayres, Montevideo, and Brazil.

The Schanschieff Electric Light and Power Company.—We understand that a petition has been presented by Mr. Barber Starkey for the revocation of a patent proposed to be purchased by the above company. Application was granted by Mr. Justice North to allow the case to stand over to enable the company to prepare their evidence, and the case has been placed in the witness list for trial.

Primary Battery Syndicates.—The *Financial News* says:—"It is reported that Mr. Newton's new electric light syndicate have entered into arrangements with Colonel J. T. North to dispose of Mr. Newton's patents to a joint-stock company with a capital somewhere in the hundred thousands. Electric lighting is about the only branch of industry in which the indefatigable Colonel has not yet embarked."

Telegraphing at Railway Stations.—In the House of Commons, on May 4, Mr. Raikes, in reply to Mr. Joicey, said there were nearly 1,600 railway stations now open for the transaction of telegraphic business during hours fixed by the companies; that in cases of emergency telegrams were, with his entire concurrence, accepted at other times and also at other stations. Such telegrams were included in the accounts with the department, and the companies received the usual commission for transmitting them.

The Writing Telegraph.—Being questioned again on this subject in the House of Commons, on Friday evening, the Postmaster-General justified his refusal to grant a license to the proprietors of the writing telegraph; but added, "If there is a substantial demand for the establishment of exchanges to be worked by the instruments of the Writing Telegraph Company, I think it preferable that they should be in the hands

Digitized by Google

of the Post Office, the instruments being supplied by the proprietors on terms to be arranged."

The Maxim-Weston Electric Light Company.—The following letter, signed by Mr. J. M. Klenck, has appeared in the financial journals:—"At a meeting of the shareholders held at Cannon-street Hotel on the 3rd inst., after Mr. Watt had vacated the chair, it was resolved to lodge a requisition with the company to call an extraordinary general meeting of the shareholders. The requisition was opened, and signed by numerous shareholders representing a large part of the capital of the company. Shareholders desirous of signing the requisition may do so by calling at my address, where it lies for signature. Provincial shareholders may have a copy of the requisition sent to them for their signature on their intimating their wish to do so."

The Paris Municipal Tariff.—The following is the tariff which the Paris Municipal Council intends to enforce in all future concessions for the distribution of electricity:—The maximum price for the electrical carcel-hour is to be 4·5 centimes, which means about 8 centimes per lamp-hour, for a 16 candle-power light. The *Revue Industrielle* remarks that the same light can be obtained from an ordinary gas burner at the cost of 6 centimes. There is, therefore, only a difference of two centimes between the price of gas and that allowed to be charged for the electric light, and if we take into consideration the cost of mains, wayleaves, and unforeseen items, &c., it is impossible to look upon this tariff as otherwise than injurious to electric lighting enterprise.

Oldham.—The Oldham Free Library and Art Gallery has been lighted by electricity since the end of January last, with 118 16 candle-power and one 500 candle-power Edison 100-volt lamps. The dynamo is placed in the gas works 150 yards away, and an insulated cable is carried overhead. The dynamo is one of Hall's No. 6 C machines, compound-wound, and gives 96 amperes at 110 volts at 720 revolutions, and is driven by an old horizontal engine, which in the daytime does duty for the ordinary requirements of the gas works, and has been in regular work for the last 24 years. The dynamo is made, and the whole installation has been carried out, by Messrs. S. Charlesworth and Co., electrical engineers, Richmond Hill Iron Works, Oldham.

Exports of Telegraphic Wire, &c.—Notwithstanding the favourable results of the Board of Trade returns, especially under the head of metals, &c., which, according to the figures issued this week, show an increase of £263,339 for April, and £1,271,572, or 12 per cent., for the four months, our exports of wire and telegraphic apparatus continue to compare unfavourably with the corresponding figures of the two previous years. The following is a comparative statement of exports of telegraphic wires and apparatus connected therewith:—

	1886.	1887.	1888.
Jan. 1 to March 31 ...	£124,074	... £131,879	... £88,077
April	111,847	... 27,616	... 27,012
Four months	£235,921	£159,495	£115,089

The School of Electrical Engineering, Hanover-square, W.—A very satisfactory report has just been received by the managers from the external examiner, Mr. H. R. Kempe, of the General Post Office, showing that out of fourteen students of the advanced class who went in for the final examination, held on April 18, in which 70 per cent. of the marks is required, eight obtained the Vellum Certificate, with the following percentages:—H. F. S. Crawford, 94·6; A. H. French, 88·6; T. W. Watts, 88; A. O. Jensen, 87·3; H. A. M'Causland, 86; E. L. Simpson, 85·3; E. H. Greg, 80·6; A. E. Beddoe, 71·3. About two months ago, as the result of an examination in engineering, the following students had also obtained the Vellum Certificate:—L. M. Green, 97·3; H. E. Taylor, 97·3; P. T. Heath, 90·6; H. A. Irvine, 88·6; R. Cotton, 87·3.

Royal Institution of Great Britain.—At the general monthly meeting held on Monday, May 7, 1888, Sir James Crichton Browne, M.D., LL.D., F.R.S., Vice-President, in the chair, the following vice-presidents for the ensuing year were announced:—Sir James Crichton Browne, M.D., LL.D., F.R.S.; William Crookes, Esq., F.R.S.; Warren de la Rue, Esq., M.A., D.C.L., F.R.S.; Colonel James A. Grant, C.B., C.S.I., F.R.S.; Sir Frederick Pollock, Bart., M.A.; John Rae, M.D., LL.D., F.R.S.; Henry Pollock, Esq., treasurer; Sir Frederick Bramwell, D.C.L., F.R.S., honorary secretary. John Tyndall, Esq., D.C.L., LL.D., F.R.S., was elected Honorary Professor of Natural Philosophy. The Right Hon. Lord Rayleigh, M.A., D.C.L., LL.D., F.R.S., was elected Professor of Natural Philosophy.

Bradford.—At a meeting of the Bradford Town Council, on May 8, Alderman Fredk. Priestman said he had expected to be able to bring before the Council a resolution accepting tenders for the execution of the works for electric lighting; but it was found necessary to extend the period during which tenders might be sent in. No less than 61 tenders had been received for the whole of the work, inclusive of buildings, and 140 for sections of the work. An unexpected difficulty had arisen. As a mere matter of form, the Town Clerk applied to the Local Government Board, and the officials appeared to have taken up the question *de novo*, demanding answers to all sorts of questions, and would perhaps send an inspector down to see whether the works were necessary or not, although the Corporation had authority under an Act of Parliament to undertake them. At present, therefore, they were at a deadlock in the matter, and he was afraid they would not get over the difficulty till a deputation went to see Mr. Ritchie. Personally, he had no doubt it was the action of some official who thought he must do something for what he got.

Electric Light v. Gas.—We have received the following communication from Mr. Henry Willmott:—"Having had 30 years' experience of billiard life I venture to give my opinion as regards lighting billiard rooms by electricity in preference to gas. It was thought some few years ago an impossible feat to light a room satisfactorily in this way, and I also shared in that opinion; but this system has lately been adopted in a new room, The Belgrave, Spur-street, Leicester-square, and is in every way advantageous on the score of cleanliness and cost, and what is still more important, *health*. The flickering so often observed with gas is entirely removed. Had this grand invention been known and acted on sooner it might have prevented the loss of many lives of those players who are fond of the game, and also spared many markers who have succumbed in consequence of the foul atmosphere arising from burnt gas, more particularly in the winter months. Under the new system my room is as cool at the end of the evening as it is at the commencement, and gentlemen customers who frequent the room speak in the highest terms of its comfort. Any gentleman who would like to visit it can have ocular demonstration of these facts. I may further add that the whole establishment is lit up in a similar manner."

The Discovery of a Sunken Rock in the Red Sea.—The recent discovery of a coral reef 15ft. below water in the Red Sea is of special interest and importance to the Submarine Cable Companies whose ships are continually cruising in those waters. We believe that the Eastern Telegraph Company's vessels have repeatedly taken soundings in the immediate

Digitized by Google

vicinity of this dangerous reef. The following is the notice which has been published by the Hydrographic Department of the Admiralty:—"Telegraphic information has been received from Lieutenant and Commander T. F. Pullen, H.M. surveying vessel 'Stork,' that he has found a small coral patch, with a least depth of 15ft., situated in latitude 14° 22′ 8″ N., longitude 42° 41′ 32″ E. Vessels passing down the Red Sea should keep to the westward of this rock, and should remember that irregular lateral currents sometimes set across the sea; and if when on the homeward voyage they pass eastward of Abu Ail, care should be taken to steer to the westward after rounding that island, until Jebel Zukur summit bears about S.S.E. ½ E. There is little doubt that the loss of the 'Avocet' was due to one of the lateral currents above mentioned, as not only was the steam vessel 'St. Oswald,' in company with the 'Avocet,' also to the eastward of the correct track, but other vessels passed on both sides of the two vessels while stopped to save the crew of the 'Avocet.'"

Science in the City.—At the house dinner on Tuesday of the City Liberal Club, Walbrook, Lord Thurlow, F.R.S., the chairman of the Anglo-American Brush Corporation, presided, and was supported by, among other gentlemen, Dr. Silvanus Thompson and Mr. J. W. Swan. The speeches were entirely non-political, relating solely to science applied to industrial purposes, and chiefly to electricity. The chairman proposed the toast of the evening, "Scientific Industries," and referring to the exceptionally appropriate character of the metropolis for such an assembly, observed that London could not be fed without railways, and that railways could not be run without the telegraph, while nearly half the business of London could not be carried on without the telephone. Speaking of the electric light, he said it would probably confer much greater blessings on the whole community of London than the people of the metropolis were aware of. It would infallibly take its place as the universal lighting agency of this great city sooner or later. Some unfortunate words in the Act of 1882 had hindered the progress of the electric light in this country until now, but the efforts which he had made to get the Act amended appeared now about to become successful.—Mr. Swan, in reply, stated that the electric light, as an established industry, was barely eight years old, and was the youngest member of a rather large family of electrical industries—the telegraph, the telephone, electro-metallurgy, &c. The light had had the misfortune to be, in some sense, an "infant prodigy," and because it had not realised all the extravagant expectations which were formed at the outset respecting it, a shade of disappointment had been created. Great progress had, however, been made, notwithstanding the numerous difficulties which had to be encountered. It had advantages over gas in purity and safety, and on the score of cheapness alone it could in some cases beat gas. Before long he hoped the light would be brought within the reach of everyone by means of central stations. He thought there was an admirable field for the application of electricity in connection with the working of the underground railways, and Mr. Chadwick had just reminded him that the electric light would probably be of great advantage used in collieries.—Dr. Silvanus Thompson, whose name was also coupled with the toast, said that he had electricity as his main subject of daily existence at the Finsbury Technical College; Mr. Swan had spoken entirely—but naturally—about the incandescent form of electric lighting; but he (Dr. Thompson) could not forget that for public uses there was the older form of lamp, the arc lamp. As soon as the Act of 1882 was amended, he believed there would be a great development of arc lighting. Though not behind other countries in electric lighting, we were very far behind the United States in the development of the telephone. Mr. Swan had forestalled him in remarking on the interesting subject of the use of electricity on the underground railways.

The Electric Light and the Gas Companies.—At the annual meeting of the Imperial Continental Gas Association the chairman (Sir Julian Goldsmid, Bart., M.P.), dealing with this subject, spoke as follows:—Now I will come to the question of the electric light. I am told that a gas company has no business to do anything to improve the electric light. I do not think that that is a proposition which will be accepted by the shareholders. I believe if we do not assist, within our reasonable powers, when it is our business to do so, that some one else will step in and take our place. For that reason I advised the Board, and the Board adopted my advice, to go into the business of electric lighting at Vienna, although it might not be altogether profitable; and I do not conceal my intention, if the contracts require it, and if the circumstances induce me to think that the interests of the association require it—I do not say that I will not do it again elsewhere. It appears that for a few days last year the Opera House at Vienna was closed in consequence of the defects in the boilers, which were supplied by an Austrian firm. This gave the authorities reason to complain, and gave us some cause for anxiety. The authorities were a little nervous, and they ordered us to close the house when in the opinion of competent engineers it was not necessary to do so. The result was that we and others were put to considerable expense. I made it my business to investigate that matter, and I think we have abundantly proved to the contractors and everybody else who had to do with the matter that we were not at fault, and that it lay with those who supplied the boilers, which were taken back at no expense to ourselves. We have now supplied Babcock and Wilcox boilers, made in Scotland, which I believe are working satisfactorily. When we have got over some technical difficulties—and they are diminishing every day—and when the two theatres are lighted, I believe we shall be giving as satisfactory a light as we have been giving in the Opera House. The light there is the finest of the kind in any part of the world, and, although the station does not pay the interest on the capital laid out, you will understand that only a third is employed, as we have not yet lighted the second theatre and the Government buildings adjoining, and it is yet impossible to judge what the total result of the central station will be. I believe it will accomplish what we thought it would. Upon the whole, I think the business was undertaken in the right spirit, and, notwithstanding the critics, I am prepared to defend it. . . . It is of no use to look behind. Invention and progress are the order of the day, and in the future invention and progress must continue to be the order of the day with all subjects connected with lighting. I referred on a former occasion to some observations made by a valued friend of my own, who, in his time, was, and is still, looked upon as a great authority on matters of this kind—I mean the late Sir William Siemens. No one disputes the fact that he was an authority on all subjects connected with electricity, as well as on all subjects connected with gas lighting. Well, he always maintained that there was a great future before the electrician and electricity, and that it would be found that it would not interfere with, but promote the business of the gas maker. That also being my opinion, I have acted upon it, and the Board have acted upon it, as I have indicated to you, in carrying out the indispensable policy of the Association, and with the best results, and in so doing, in my judgment and in their judgment, we have acted right.

ELECTRICAL OSCILLATIONS.

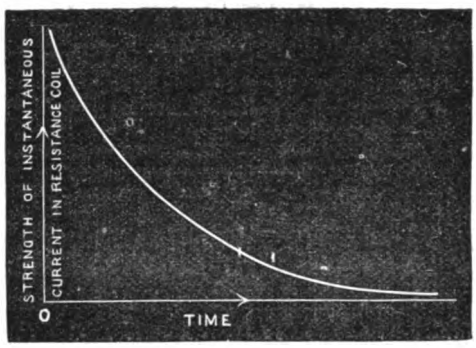
BY J. A. FLEMING, M.A., D.SC.

The important question of discharge through lightning conductors, as well as that of the behaviour of conductors generally towards brief or very rapidly reversed electromotive forces, makes it desirable for electrical students to understand the conditions under which so-called *electrical oscillations* take place in conductors. We may advantageously begin an elementary explanation of the subject by considering a mechanical or rather a pneumatical analogy. Suppose there be two large vessels, or reservoirs, connected by a pipe, closed or closable in the middle by a stopcock. Let one of these vessels, A, be exhausted of its air, and let the other, B, have air in it at the atmospheric, or a greater than the atmospheric pressure. *First*, let the connecting pipe be supposed to be long and narrow; on opening the stopcock air will rush over from B into A, and the flow of air will continue uniformly in the pipe in one direction until the pressure in A and B is equalised. *Second*, let the connecting pipe be very short and large, so that little tubular friction is offered to the flow of air. Under these circumstances the result of opening the top would be that a rush of air would take place, which would be succeeded by a series of oscillations of the air in the tube. The air, in fact, rebounds from side to side, and the equilibrium is only finally established after a series of gradually diminishing oscillations or backward and forward currents of air in the tube. This establishment of equilibrium of pressure by oscillatory movement takes place when the resistance to the flow is small. That this is no fanciful description is proved by the experience of MM. Clément and Désormes in their experiments to determine the ratio of the specific heats of gases. In these experiments a large glass vessel has a partial vacuum made in it. A stopcock is then quickly opened and closed, and the pressure of the air determined after a short time. These experiments were also carried out by MM. Gay Lussac and Welter. See *Journal de Physique*, LXXXIX., 1819, 428, and *Ann. de Ch. et de Phys.* [I], XIX., 1821, 436.

M. Cazin (*Ann. de Ch. et de Phys.* [3], LXVI., 1862, 206) pointed out a source of error which resulted from these air oscillations, and showed that the final pressure depended upon the phase of the oscillation at which the stopcock is finally closed. Helmholtz (*Die Erhaltung der Kraft*, 1847) seems to have been the first to conceive that when a condenser was discharged through a resistance the electrical discharge conducted itself after the fashion of the establishment of pressure equilibrium in the experiment above described on the specific heats of gases. Sir William Thomson took up the question in 1855 (*Phil. Mag.*), and discussed it in a remarkable paper.

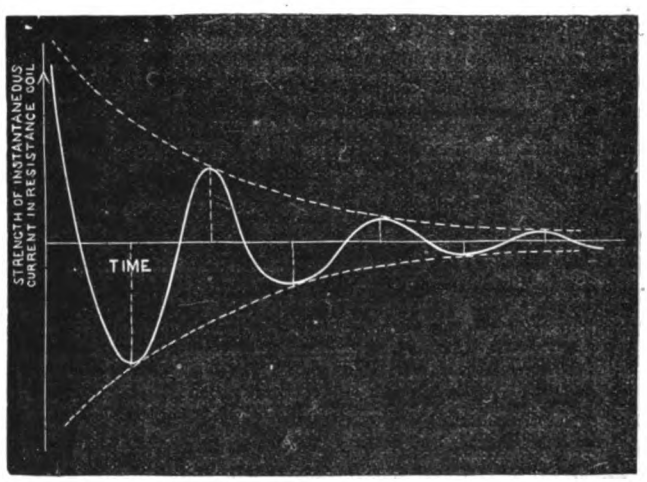
In this important monograph, he considers mathematically the discharge of a condenser through a resistance, and arrives by very ingenious reasoning at the conclusion that when the resistance has a value greater than a certain critical one, the discharge of the condenser will consist in a current which flows uniformly in one direction out of the condenser, dying gradually away in strength according to a certain law. If, however, the resistance is less than the critical one, then the discharge of the condenser consists in a series of waves of electric current, first in one direction and then in the other, each short current being less in maximum than the last. During equal intervals of time the quantities of the alternate discharges decrease in geometrical progression. Graphically, these two cases might be represented by two curves—one an exponential curve (Fig. 1) and the other a periodic curve (Fig. 2). In the first case the current at any instant in the resistance coil is represented by the ordinates of a logarithmic curve which descends gradually to the axis. In the second case, the instantaneous current strengths are represented by the ordinates of a periodic curve, whose maxima descend in geometric progression as the time increases in arithmetic progression. This second form of discharge is called the *oscillatory discharge*.

The foregoing predictions of analysis have been confirmed by the experiments of Feddersen, Paalzow, Bernstein, Blaserna, Helmholtz, and Schiller. Thomson in his original paper pointed out and suggests the application of Wheatstone's mirror to the examination of the discharge. In Feddersen's experiments the spark from a Leyden jar battery was taken between two brass balls placed in front of a revolving mirror. The discharge was passed through a high resistance. The image of the spark was viewed by a telescope. Under these circumstances the image of the spark was drawn out when the mirror revolved into a continuous band of light in a direction perpendicular to that of the discharge. When the resistance was reduced a point was reached at which the image was broken up into a series of separated strips, each strip corresponding to a discharge. This showed that the discharge was intermittent.



Curve representing the Discharge of a Condenser through a Large Resistance. Discharge Unidirectional and Continuous.

FIG. 1.



Curve representing the Discharge of a Condenser through a Small Resistance. Discharge is Periodic and Alternate. Maxima gradually diminishing in Geometric Progression.

FIG. 2.

In Paalzow's experiments a similar discharge from a Leyden battery was passed through a resistance coil and through a vacuum tube, and the image of the discharge in the vacuum tube viewed in a revolving mirror. As before, with a small resistance the image consisted of a number of separate images, each of which corresponded to a discharge, and a bluish light showed itself at both poles of the vacuum tube. When the resistance was increased the bluish light showed itself only at one pole. In the former case a magnet held outside the tube split the discharge into *two* lines of light, showing that it consisted of currents travelling in both directions; but in the last case the magnet did not divide the discharge. This sufficiently indicated that with a low resistance the discharge was oscillatory, and not uniform or unilateral.

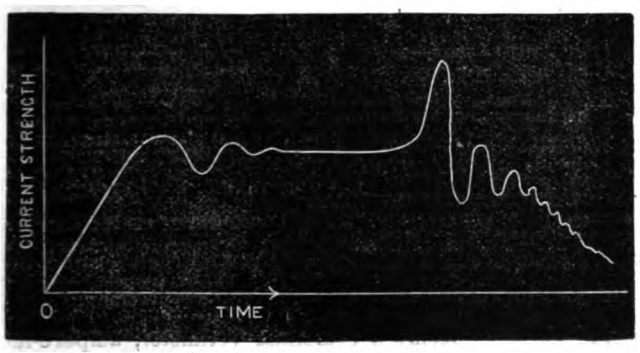
Feddersen found that the critical resistance at which the discharge just becomes oscillatory varies inversely as the square root of the capacity of the battery, which is in agreement with the predictions of theory.

Helmholtz and Schiller have investigated the nature of the induced currents produced in the secondary of an induction coil under certain conditions as to resistances and coefficients of induction, and found that under certain conditions the induced currents consist of a series of oscillations gradually dying away.

Digitized by Google

Blaserna also examined the nature of the flow when a current is being established in an inductive circuit, and found that in such a circuit the establishment and interruption of a current may take place by a series of oscillations which may be roughly graphically represented as in Fig. 3. In his experiments the duration of an oscillation was about $\frac{3}{10000}$th or $\frac{4}{10000}$th of a second, and about 50 to 100 oscillations took place before the current was established. Blaserna's experiments were undertaken in 1870 (*Phil. Mag.*, Series IV., Vol. XXXV., p. 318), and in the *Phil. Mag.*, Series IV., Vol. XLII., 1871, is a paper in which Helmholtz has examined and criticised some of Blaserna's results. Other references are to Paalzow, *Pogg. Ann.*, 1861, and Bernstein, *Pogg. Ann.*, 1871; and Schiller, *Pogg. Ann.* 1874, to which the student may be referred for full details, In "Wiedemann's Galvanismus," §§ 801, &c., a good general account of Blaserna's researches will be found.

It is a deduction from theory that if a condenser of capacity C be discharged through a wire of inductance L, and resistance R, that the discharge becomes oscillatory when R is less than $\sqrt{\frac{4L}{C}}$. If R is greater than $\sqrt{\frac{4L}{C}}$ the duration of the discharge is prolonged, and the oscillations quenched. In addition to the paper of Sir William Thomson, above referred to, the student will find a mathematical discussion of the problem on pages 512 *et seq*, of Mascart and Joubert's "Electricity" (Atkinson's translation), and in the article "Electricity," *Encyclopædia Britannica*, 9th Edition, by Prof. Chrystal, and a short discussion of it in a paper by the writer on "Networks of Conductors," *Phil. Mag.*, Sept., 1885, and *Proc.* Physical Society, London, 1885. It may be noted, however, in passing, that in all these investigations the inductance L is assumed to be a constant, independent of the current.



Curve representing the Establishment and Interruption of a Current by a Constant E.M.F. in a series of Electrical Oscillations.

FIG. 3.

Some practical consequences of the fact that such condenser or Leyden jar discharges are generally oscillatory have scarcely received the attention due to them. In experiments on the magnetisation of sewing needles by sending round them the discharge of a Leyden jar through a solenoid of insulated wire, it has been frequently noticed that there is an irregularity in the direction of the polarity produced. These irregularities are only what might be expected when we recognise that in such cases we may be operating with an oscillatory discharge. It has been frequently remarked that a stroke of lightning will demagnetise compass needles, and magnetised sewing needles can be demagnetised by sending through them a powerful discharge. In this case the oscillatory nature of the discharge makes it really consist of a rapidly reduced series of alternate currents. Just as a magnetised watch may be demagnetised by placing it in a coil traversed by an alternate current and drawing it gradually away from the coil, and thus submitting it to gradually reduced alternate magnetisation, so in a similar manner an oscillatory discharge may become a powerful demagnetising agent.

Let us follow the predictions of this theory into a few possible consequences. For a condenser of given capacity, charged to given potential through a wire of inductance L and resistance R, the discharge is *continuous* when L is less than $\frac{R^2C}{4}$, and *oscillatory* when L is *greater* than $\frac{R^2C}{4}$.

Suppose a long wire of resistance R, used as a discharging wire, is first stretched out into a single loop, and secondly coiled up into a coil of maximum inductance, it might be possible that R and C should have such values that in the first case the discharge is continuous, and in the second oscillatory. For circuits of equal inductance the discharge is rendered continuous by increasing the resistance. Hence, a discharge which was oscillatory when made through a copper discharging circuit might become continuous when made through a German silver circuit of equal form and diposition.

It is not difficult to show that at the first instant when the discharge is commencing in the circuit, the counter-electromotive of self-induction of the discharging circuit is equal to the potential difference of the condenser plates, and that the rate of diminution of the counter-electromotive of self-induction is equal numerically to the *reciprocal of the time constant* of the discharge circuit; hence, the greater the time constant the less rapidly is the counter E.M.F. of self-induction removed.

The remarkably interesting experiments of Dr. Lodge on electrical discharges, which he brought before the Society of Arts in the Mann Lectures given on the 10th and 17th of March last, have given the most striking illustration of the surprising and apparently paradoxical results which may arise from the phenomena of oscillatory discharges. In Dr. Lodge's experiments the most startling effect is that two conductors placed near each other, which are connected together by a copper wire, will, if suddenly brought to very greatly different potentials, prefer to discharge through the air in the form of a spark rather than neutralise their potential differences quietly through the wire in the form of a current. The reason for this is to be sought in the fact that the resistance operator of the copper wire or what may, somewhat loosely speaking, be called its instantaneous resistance, is nearly infinite for potential differences very suddenly applied to its ends. The most interesting result is, however, the comparison of the behaviour of conductors of iron and copper. It is now generally well understood that an iron conductor possesses for moderately great periodic, and for steady electric currents a greater impedance than does a copper conductor of equal size. The circular magnetisation of the iron conductor by the current is, of course, the cause of this greater inductance. It might, then, have been reasonably supposed that an iron conductor would be even worse than a copper one in preventing the sudden neutralisation of potential difference of bodies connected by it. The reverse is, however, found to be the case. Iron seems to offer less obstacle to a sudden discharge than copper. The explanation of this, which appears on the face to be at least probable, is that the magnetisation of iron is an effect which takes time. In other words, magnetisation lags behind magnetising force, and if a magnetising force is very suddenly applied and withdrawn, the iron has not time to respond to the force acting on it. Hence, iron is practically non-magnetic for very sudden and brief magnetising forces. A parallel may be found in the behaviour of air to prolonged and very sudden disturbances. If a piece of gun cotton is laid on a board and ignited by a match, the gun cotton burns away with comparative slowness, without damage to the board. It produces a volume of gas which displaces air gently and gradually. If the gun cotton is fired by a detonator with great rapidity, it blows a hole in the board, the reason being that the air has not time to be displaced, and offers an immense resistance to the sudden upward explosion, so that nearly the whole effect of the explosion takes place downwards. In the electric experiment, if the two bodies connected by the iron or copper wire were brought up to difference of potential rather slowly, the effect would be to produce a current in the conductor; but if they are brought up with extreme rapidity the impedance of the conductor is so enormous that practically the whole discharge takes place across the air space between the conductors. To return to the peculiar case of iron. The non-magnetisability of iron to very sudden and very brief magnetising forces renders its inductance equal to or not greater than that of, say, copper. Its greater specific resistance then makes its time-constant less than that of an otherwise equal copper conductor, and therefore the *rate* at which the counter-electromotive force

Digitized by Google

of self-induction dies away is greater in iron than in copper conductors of equal size and conformation; and hence the iron conductor is able to draw down faster to equality the potentials of the conductor to which the ends are attached, and therefore to reduce their tendency to spark across or discharge to one another through the air.

In Dr. Lodge's experiments the two conductors were the two outer coatings of two Leyden jars on the terminals of a Voss inducto-static machine. The inner coatings of these jars were in connection with the + and − terminals of the machine. The outer coatings of these jars were connected by a long wire and also to two discharging rods whose distance could be varied. When the handle of the machine was turned the jars became charged respectively with +E and −E. The outer coatings then possessed also oppositely-named charges, which in the language of palæozoic electricians would have been called "bound" electricity. If the inner coatings of the jars are connected these "bound" charges on the outer coatings become suddenly "free." Although, however, these outer coatings are connected together by a metallic circuit, viz., the long wire, the discharge prefers to take the route across the air space between the points or balls of the discharger rather than through the wire, because that wire offers such enormous impedance to sudden and brief currents.

In respect of the passage of electric currents we are bound now to recognise three well-marked differences in the behaviour of conductors. First, when the current is a steady current the phenomena of current flow is then regulated by the ohmic resistance; secondly, when the current is periodic or of moderate duration, when the phenomena is regulated in addition by the inductance of the circuits; third, when the conductor is submitted to discharges of very brief duration, when the inductance almost wholly determines the behaviour.

In those cases, therefore, such as lightning conductors, in which the very object of the arrangement is to conduct, inductance comes in as an opposing action, and renders a conductor virtually non-conductive for brief discharges. Hitherto it has been supposed that flat bands of copper formed the best arrangement for passing such instantaneous currents, and iron has been rejected because of its supposed greater inductance and less resistance. All these experiments of Dr. Lodge indicate, however, that this preference for copper has been founded on insufficient knowledge, and that for these rapid discharges iron is as non-magnetic as copper and possesses superior advantages in its greater specific resistance, higher melting point, and less cost. The only way in which the inductance of a circuit can be lessened or neutralised is by the addition of electrostatic capacity. If a condenser is arranged in series with a circuit, such as an electro-magnet, possessing large inductance, it is possible by a certain proportion between the inductance and capacity to neutralise the inductance of this circuit for periodic currents of given frequency; and in the same way a sufficiently large capacity bestowed upon an inductive circuit would enable it to transmit very brief discharges freely. In this case what we virtually do is to give the conductor a certain elasticity, and instead of resisting strongly a sudden electromotive impulse it yields to it, and permits the generation of a current. It may be that we have here a partial explanation of the fact that even if the terminals of the secondary wire of an induction coil are short-circuited by a wire of no very great resistance, yet a very sensible shock is experienced on touching with the two hands the ends of the secondary. The human body possesses a sensible *capacity*, although perhaps the origin of this may be found in the fact that the tissues are susceptible of electrolysis, and accordingly the human body possesses capacity only in the sense in which we may say a voltameter or secondary battery possesses capacity, and not a true electrostatic capacity to any great degree. The result, however, is to make the human body act like a non-inductive circuit, and very responsive, therefore, as a conductor to brief electromotive forces applied to its ends. Hence, when the two hands short-circuit a metallic circuit of very low resistance, yet sensible inductance, brief periodic electromotive forces applied to the ends of this conductor are yet felt as shocks, because the inductive metallic conductor is virtually more opaque to these than the more highly resisting yet less inductive circuit of the body. More is this apparent if a Leyden jar is discharged by a long copper wire, the ends of which are held in the bare hands. Hence the necessity for a glass handle to a discharging rod.

These researches of Dr. Lodge go far to upset current notions on the appropriate form to be given to lightning conductors, and they point to the fact that the right direction of modification is to give the conductor attachment, if possible, to a conductor or condenser of large electrical capacity. Hitherto it has been assumed that the ohmic conductance of a lightning conductor is the quality on which its preservative utility chiefly depends. Our eyes are now opened to the fact that the instantaneous impedance to rapid discharges may make even a thick copper rod virtually non-conductive.

The exceedingly interesting experiments of Dr. Lodge on artificial lightning strokes produced between metallic plates, and various objects placed on one of them make it evident that old notions of a protected area round a conductor must now be considered as obsolete. The only absolute protection is obtained when the object is entirely enclosed in a metal case kept in connection with the earth. A man in armour, standing on damp ground, may be probably considered as very perfectly protected from harm by lightning stroke; but for buildings the nearest approach to security is probably to be obtained by following Dr. Lodge's suggestion to place high lightning conductors on all exposed pinnacles, turrets, towers, &c., connecting all these conductors to one another, and to all metal roofs, water courses, leads, &c.; and to fit the edges and eaves of roofs, wall tops, and ridges with barbed galvanised iron wire connected to the conductor system generally.

Protection from lightning is evidently a subject on which the last word has by no means been said, and Dr. Lodge's contribution to it is one of the most important of recent additions to practical knowledge.

ON A NEW COMPOSITE ELECTRIC BALANCE.*

BY SIR WILLIAM THOMSON, F.R.S.

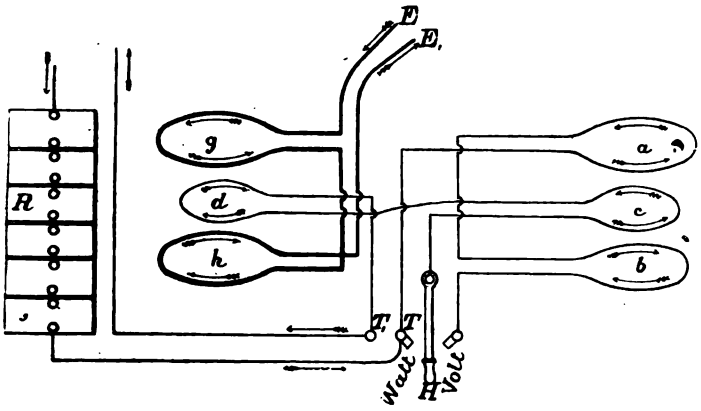
This instrument has been designed for the purpose of providing, in one instrument, the means of (*a*) measuring the difference of potential between two points of an electric circuit, as, for instance, the difference of potential between the supply conductors of an electric light installation, (*b*) the current flowing in such a circuit, and (*c*) the rate of working in the circuit. The instrument thus forms a combined voltmeter, ampere-meter and wattmeter. The general form of the instrument is similar to that of the standard centi-ampere or deci-ampere current balances, and it consists of (1) two coils of silk-covered copper wire fixed one above the other, with their planes horizontal on a slab of slate, (2) two coils of similar wire made up in the form of anchor rings and fixed to the ends of a balance beam, (3) two coils fixed similarly to (1) but capable of carrying currents up to 500 amperes. The beam of the balance is suspended by two flat ligaments of fine copper wire in such a position that one of the coils fixed to the ends of the beam is suspended midway between the fixed pair of fine-wire coils (1), while the other suspended coil is similarly placed relatively to the thick wire or current coils. When the instrument is used for the measurement of alternating currents, the current coils are made by two or three turns of a stranded conductor. Each wire of the stranded conductor is covered with silk, so as to insulate it from the others, and in order as far as possible to annul the effect of induction in causing the current to be different at different distances from the axis of the conductor the strand is given one turn of twist for each turn round the coil.

The arrangement of the connections in the instrument will be readily understood from the figure, which shows diagrammatically the arrangement of the coils. In this figure *a* and *b* represent the fixed fine-wire coils, *c* and *d* the suspended coils, and *g* and *h* the current coils. The instrument is joined in the circuit through a suitable anti-inductive resistance, R, through which the current passes to the terminal T, from

* Abstract of a Paper read before the Philosophical Society of Glasgow.

Digitized by Google

which the course of the current through the coils to T_1 is indicated by the arrows in the diagram, the switch handle H being in this case turned to "volt." For the measurement of amperes the switch is turned to "watt," the measured current passed through the suspended coils of the balance, and the currents to be measured passed through the coils *g*, *h* by introducing the electrodes E, E_1 into the circuit. The current through the suspended coils may sometimes be measured by means of the instrument itself, arranged for the measurement of volts. This may be done by first measuring the current which the difference of potential between the supply conductors of an electrical installation, or between the poles of a battery, causes to flow through the fine coils of the instrument and its external resistance, and then turning the switch to "watt," and, at the same time, introducing a resistance into the circuit equal to the resistance of the fixed coils. When the balance is used as a wattmeter the switch is turned to "watt," and the terminals T, T_1 joined to the supply-conductors, while the current through the circuit is passed through the coils *g*, *h*. When the rate of working in an alternate-current circuit is measured by such a balance, the anti-inductive resistance R must be so great that there is no sensible difference of phase



between the currents flowing through the fine-wire coils of the instrument and the electromotive force on the supply-conductors to which they are connected.

JUVENILE LECTURES.

THE APPLICATION OF ELECTRICITY TO LIGHTING AND WORKING.*

BY W. H. PREECE, F.R.S.

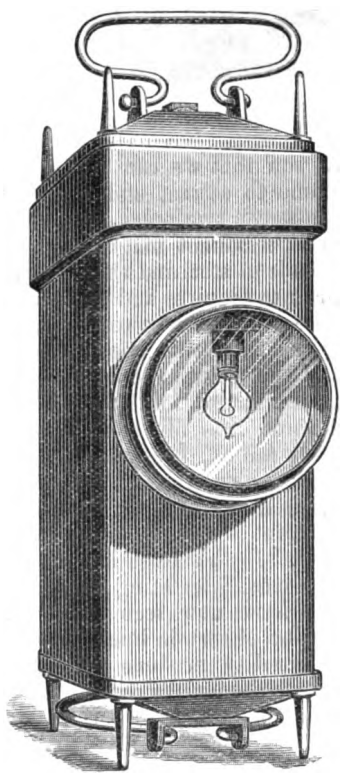
Lecture II.

(Continued from page 738, Vol. XX.)

Last Wednesday I had the pleasure of showing you how electricity was employed to produce heat, and how, by means of the heat resulting from the passage of electric currents, we obtained light. To-night I intend taking you in a different direction altogether. I want to disabuse your minds of the idea that electricity is a prime mover in the sense we generally consider prime movers to be. It is nothing of the sort; it is simply an agent or a medium by which energy, such as I showed and described to you last Wednesday, can be passed through one of its stages. The first form of energy that I am going to call your attention to to-night is of the character generally called work. It means something done; objects moved, resistance overcome.

In all these actions of electricity that I am going to show you—if an electric current, for instance, moves a magnet, a magnet moved will produce electricity; if an electric current, as I showed you last Wednesday, produces heat, heat in its turn will produce electricity, and so we have throughout the whole range of mechanics and of science this principle of reversibility introduced. For another instance, suppose we compress air or gas, the gas always reverses the action, and exercises a reaction precisely equal in amount to the action that caused the compression. Take a letter-weight. If you want to weigh a letter you do so simply by compressing a spring, and the weight of the letter is measured by the reverse action of the spring in pressing the letter upwards. If you take a weight and lift it, wherever it may be, that weight is in a position to produce the reverse action. If we take two magnets or two currents of electricity and forcibly separate them, there is also always this reaction between them.

PITKIN'S LAMP AND BATTERY. For description see preceding Lecture.



SCHANSCHIEFF BATTERY AND LAMP. For description see preceding Lecture.

I will first of all once more refer you to the hand-dynamo, which will work and produce currents of electricity that will enable me to produce on the table before you some effects. Last week I showed you how we could obtain heat. To-night, as some of the effects I want to show you are rather minute,

* A course of three Lectures delivered before the Society of Arts on January 4th, 11th and 18th.

Digitized by Google

my friend, Mr. Lant Carpenter, has undertaken to assist me by throwing upon the screen behind me certain pictures conveying more vivid ideas of what I want to express than if I were to attempt to do so with the small apparatus that I have on the table.

I want, in the first place, to show you what is meant by a magnetic-field. We have now on the screen the projection of a steel magnet; it has been charged with magnetism, and as Mr. Carpenter now scatters over a glass placed above that magnet some very fine iron filings, you see that they arrange themselves in straight lines and curves, and when the glass is gently tapped, those lines all arrange themselves in a radial fashion, with beautiful symmetry, in the most wonderful way, every particle being directed by attraction towards the pole (Fig. 7). From that I want you to see how those lines picture to us the conditions of the space that surrounds every magnet, and in every single experiment that I am going to show you to-night the currents that we obtain are currents due to the fact that we can force copper conductors to pass through what is called a magnetic-field; the neighbourhood of a magnet, such as you saw just now on the screen, is called a magnetic-field. Whenever a copper conductor, such as the wire I now have in my hand, or a wire arranged in other forms, is caused to pass through a magnetic-field, it becomes electrified, it acquires that condition which enables us to obtain currents, and to use those currents.

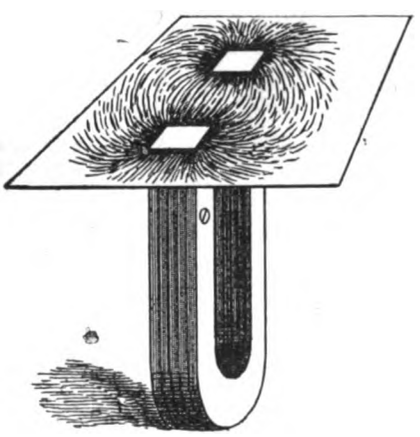


FIG. 7.

I will now show you that we can utilise currents produced by this hand-dynamo to attract and repel particles of iron. You now see on the screen two poles of an electro-magnet; the difference between a permanent magnet and an electro-magnet is that the one is made of steel and the other of soft iron. The permanent steel magnet acquires and retains its magnetism for a long time, whereas in an electro-magnet the magnetism only exists during the time that the current is passing round the soft iron core. The picture shows the two coils of copper wire which, with their cores, form the electro-magnet. Mr. Carpenter places some iron filings on that magnet, and on raising it they simply fall off, because there is no power present to attract them; I now cause a current to pass, and the iron filings being presented they are attracted, and continue so as long as the current is passing. The moment the current ceases the filings fall. In that experiment we have seen one of the simplest and most interesting elementary experiments in electricity. You have now seen that in a magnetic-field we have the production of certain lines of magnetic force, and that currents of electricity produce magnetic-fields. I want now to show you that whenever a conductor is passed through a magnetic-field, work is done upon the conductor, it receives a kind of reaction, currents of electricity are produced. Similarly, if the conductor be placed in the magnetic-field and the current from another source be passed through it, it is urged to move in a certain direction. I am going to show you the instrument itself if I can, but Mr. Carpenter has a similar instrument in the lantern, and the experiment will be repeated before you in another and different form on the screen.

The fact that I want you to understand is, that whenever we pass a current of electricity through a conductor in the neighbourhood of a magnet, or in a magnetic-field, it has a tendency to be moved or to rotate around that field in a definite direction. Here I have a horseshoe magnet; it is surrounded by a cage of copper wire, and through that cage I will cause a current of electricity to flow. You now see that the coils are rattling round at a rapid rate. I take the current off, and they stop; I put the current on again, and away they go. There you have an illustration of the fact that whenever you have a conductor in a magnetic-field, and the conductor is traversed by a current of electricity, it is always urged to move.

I ought to point out to you that here we have the basis of every single experiment I am going to show you to-night. A current of electricity produced rotation, as you saw, in that cage, and in this particular form that I want to show you on the screen you will see that rotation is produced in another way. You now see the apparatus on the screen. On the left and right hand side there are two upright columns, the poles of the magnet, exactly similar to the one I showed you on the table. Between those two poles there is an iron armature rotating on a centre point, and that armature is enveloped at each end by a small coil of copper wire. When a current of electricity passes through that copper wire it magnetises the iron bar, and the iron bar gets attracted and repelled by the two poles of the magnet, so that on my now putting the current on, you see, away it goes. The application of that principle has been carried out in the little apparatus I have here, called Froment's motor. This particular Froment's motor is used to wind a clock; in fact, it has only just been taken from a clock which, at twenty minutes past every hour, was wound up by a current of electricity actuating this motor. By its means the hand-winding of clocks is dispensed with, and, supposing a battery will last for years, so the clock will keep time for years without one being troubled by the necessity of going round the house and winding up the clocks. In order to show you, in a pretty way, one effect of this rotation, I have, through the kindness of Mr. Apps, brought here a motor which works a disc on the front of which some vacuum tubes have been fixed. Here is an induction coil which will produce currents of electricity that pass through these vacuum tubes and illuminate them, and when, by means of the motor, I cause the disc to rotate, you see what beautiful optical effects the persistence of vision produces when you look at electric sparks passing through vacuum tubes filled with a very slight proportion of different gases.

(To be continued.)

EFFECT OF CHLORINE ON THE ELECTROMOTIVE FORCE OF A VOLTAIC COUPLE.*

BY DR. G. GORE, F.R.S.

If the electromotive force of a small voltaic couple of unamalgamated magnesium and platinum in distilled water is balanced through the coil of a moderately sensitive galvanometer of about 100 ohms resistance, by means of that of a small Daniell's cell, plus that of a sufficient number of couples of iron and German silver of a suitable thermo-electric pile (see *Proceedings* Birmingham Philosophical Society, Vol. IV., p. 130), the degree of potential being noted, and sufficiently minute quantities of very dilute chlorine water are then added in succession to the distilled water, the degree of electromotive force of the couple is not affected until a certain definite proportion of chlorine has been added; the potential then suddenly commences to increase, and continues to do so with each further addition within a certain limit. Instead of making the experiment by adding chlorine water, it may be made by gradually diluting a very weak aqueous solution of chlorine.

The minimum proportion of chlorine necessary to cause this sudden change of electromotive force is extremely small; in my experiments it has been one part in 17,000 million parts of water,† or less than one 7,000th part of that required

* Paper read before the Royal Society, May 3, 1888.

† As one part of chlorine in 17,612 millions parts of water had no visible effect, and one in 17,000 millions had a distinct effect, the influence of the difference, or of one part in 500,000 millions, has been detected.

Digitized by Google

to yield a barely perceptible opacity in ten times the bulk of a solution of sal ammoniac by means of nitrate of silver. The quantity of liquid required for acting upon the couple is small, and it would be easy to detect the effect of the above proportion, or of less than one ten thousand millionth part of a grain of chlorine in one-tenth of a cubic centimetre of distilled water by by this process. The same kind of action occurs with other electrolytes but requires larger proportions of dissolved substance.

As the degree of sensitiveness of the method appears extreme, I add the following remarks. The original solution of washed chlorine in distilled water was prepared in a dark place by the usual method from hydrochloric acid and manganic oxide, and was kept in an opaque well-stoppered bottle in the dark. The strength of this liquid was found by means of volumetric analysis with a standard solution of argentic nitrate in the usual manner, the accuracy of the silver solution being proved by means of a known weight of pure chloride of sodium. The chlorine liquid contained 2·3 milligrammes or ·03565 grain of chlorine per cubic centimetre, and was just about three-fourths saturated.

One-tenth of a cubic centimetre of this solution ("No. 1"), or ·003565 grain of chlorine, was added to 9·9 cubic centimetres of distilled water, and mixed. One cubic centimetre of this second liquid ("No. 2"), or ·0003565 grain of chlorine, was added to 99. cubic centimetres of water, and mixed; the resulting liquid ("No. 3") contained ·000003565 grain of chlorine per cubic centimetre. To make the solutions ("No. 4") for exciting the voltaic couple, successive portions of one-tenth or one-twentieth cubic centimetre of "No 3." liquid were added to 900. cubic centimetres of distilled water, and mixed.

I have employed the foregoing method for examining the states and degrees of combination of dissolved substances in electrolytes, and am also investigating its various relations.

THE SUBMARINE TELEGRAPH ACTS.

The following Order in Council was issued on the 3rd inst. :—

WHEREAS by the 2nd Section of "The Submarine Telegraph Act, 1885," it is enacted as follows :—

"The Convention of the fourteenth of March, one thousand eight hundred and eighty-four, mentioned in the schedule to this Act as set forth in that schedule is hereby confirmed and subject to the provisions of this Act the articles of such Convention (referred to in this Act as 'the Convention') shall be of the same force as if they were enacted in the body of this Act:"

And whereas by the 2nd section of "The Submarine Telegraph Act, 1886," which was passed on the 25th of September, 1886, it is enacted as follows :—

"It shall be lawful for Her Majesty in Council at any time after the passing of this Act, to order that the declaration mentioned in the schedule to this Act as set forth in that schedule shall be of the same force, and the same shall accordingly be of the same force, as the Articles of the Convention set forth in the schedule to the Submarine Telegraph Act, 1885:"

And whereas it has been made to appear to Her Majesty that it is expedient to give effect to the declaration set forth in the schedule to "The Submarine Telegraph Act, 1886:"

NOW, THEREFORE, Her Majesty, in exercise of the power vested in Her by the said Submarine Telegraph Act, 1886, and by and with the advice of Her Privy Council, is pleased to order, and doth hereby order, that the said Declaration mentioned in the schedule to that Act, as set forth in that schedule and in the schedule hereto, shall be of the same force as the Articles of the said Convention set forth in the schedule to the said Submarine Telegraph Act, 1885.

C. L. PEEL.

Schedule to the foregoing Order.

SUBMARINE TELEGRAPH DECLARATION.

Certain doubts having been raised as to the meaning of the word "wilfully," used in article two of the Convention of the fourteenth of March, one thousand eight hundred and eighty-four, it is understood that the provision in respect of penal responsibility contained in the said article does not apply to cases of breakage or injury caused accidentally or of necessity in the repair of a cable when all precautions have been taken to avoid such breakage or injury.

It is equally understood that article four of the Convention had no other object, and is to have no other effect, than to empower the competent tribunals of each country to decide in conformity with their laws and according to the circumstances the question of the civil responsibility of the owner of a cable who in laying or repairing his own cable breaks or injures another cable, as well as the consequences of such responsibility if it is recognised as existing.

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, May 11th.

ROYAL INSTITUTION.

9 p.m. Lecture, "Building the New Tay Bridge." By Mr. W. H. BARLOW.

SATURDAY, May 12th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (5). By Mr. C. ARMBRUSTER.

PHYSICAL SOCIETY (LONDON).

3 p.m. Note on "The Condition of Self-Excitement in a Dynamo Machine," and Note on "The Conditions of Self-Regulation in a Constant Potential Dynamo Machine." By Prof. S. P. THOMPSON. Note on "The Electrical Action of Light." By Mrs. W. E. AYRTON. On "The Theory and Practice of Applying the Dynamometer to the Investigation of Transformers." By Mr. T. H. BLAKESLEY. On "Measuring the Electromotive Force of Dynamos and Motors." By Prof. W. E. AYRTON, F.R.S., and Prof. J. PERRY, F.R.S.

MONDAY, May 14th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture VI. "The Decoration and Illustration of Books" (3). By Mr. WALTER CRANE.

TUESDAY, May 15th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be discussed:—"The Tay Viaduct, Dundee." By Mr. PETER CRAWFORD BARLOW, B.A., M.Inst.C.E. "The Construction of the Tay Viaduct, Dundee." By Mr. W. INGLIS, Assoc.M.Inst.C.E. At this meeting the last ballot for members for the present session will take place.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Plant in the War of Nature" (3). By Mr. W. GARDINER, M.A.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "Emigration." By Mr. JAMES RANKIN, M.P.

ENGINEERING SOCIETY (King's College).

4:15 p.m. Paper on "High-Speed Engines." By Mr. LONG.

ROYAL VICTORIA HALL (Waterloo Bridge-road, S.E.).

8 p.m. Lecture, "William Harvey and his great Discovery of the Circulation of the Blood." By Mr. E. A. PARKYN.

WEDNESDAY, May 16th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Electric Lighting from Central Stations." By Mr. R. E. B. CROMPTON. The ATTORNEY-GENERAL, M.P., will preside.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Meeting at the Institution of Civil Engineers. The following papers will be read:—"Report of the Wind Force Committee on Experiments with Anemometers conducted at Hersham." Drawn up by Mr. G. M. WHIPPLE, B.Sc., F.R.Met.Soc., and Mr. W. H. DINES, B.A., F.R.Met.Soc. "On the Measurement of the Increase of Humidity in Rooms by the Emission of Steam from the so-called Bronchitis Kettle." By Mr. WILLIAM MARCET, M.D., F.R.S., President.

THURSDAY, May 17th.

CHEMICAL SOCIETY.

FRIDAY, May 18th.

ROYAL INSTITUTION.

9 p.m. Lecture, "La Reproduction Artificielle des Roches Volcaniques." By M. ALPHONSE RENARD.

Digitized by Google

my friend, Mr. Lant Carpenter, has undertaken to assist me by throwing upon the screen behind me certain pictures conveying more vivid ideas of what I want to express than if I were to attempt to do so with the small apparatus that I have on the table.

I want, in the first place, to show you what is meant by a magnetic-field. We have now on the screen the projection of a steel magnet; it has been charged with magnetism, and as Mr. Carpenter now scatters over a glass placed above that magnet some very fine iron filings, you see that they arrange themselves in straight lines and curves, and when the glass is gently tapped, those lines all arrange themselves in a radial fashion, with beautiful symmetry, in the most wonderful way, every particle being directed by attraction towards the pole (Fig. 7). From that I want you to see how those lines picture to us the conditions of the space that surrounds every magnet, and in every single experiment that I am going to show you to-night the currents that we obtain are currents due to the fact that we can force copper conductors to pass through what is called a magnetic-field; the neighbourhood of a magnet, such as you saw just now on the screen, is called a magnetic-field. Whenever a copper conductor, such as the wire I now have in my hand, or a wire arranged in other forms, is caused to pass through a magnetic-field, it becomes electrified, it acquires that condition which enables us to obtain currents, and to use those currents.

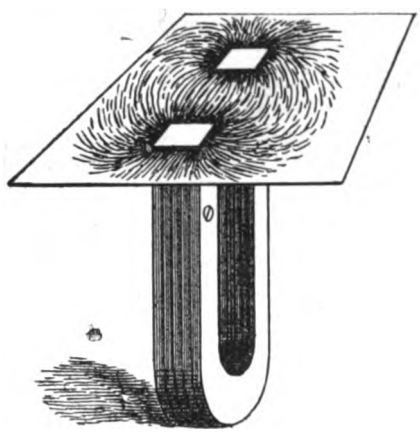

FIG. 7.

I will now show you that we can utilise currents produced by this hand-dynamo to attract and repel particles of iron. You now see on the screen two poles of an electro-magnet; the difference between a permanent magnet and an electro-magnet is that the one is made of steel and the other of soft iron. The permanent steel magnet acquires and retains its magnetism for a long time, whereas in an electro-magnet the magnetism only exists during the time that the current is passing round the soft iron core. The picture shows the two coils of copper wire which, with their cores, form the electro-magnet. Mr. Carpenter places some iron filings on that magnet, and on raising it they simply fall off, because there is no power present to attract them; I now cause a current to pass, and the iron filings being presented they are attracted, and continue so as long as the current is passing. The moment the current ceases the filings fall. In that experiment we have seen one of the simplest and most interesting elementary experiments in electricity. You have now seen that in a magnetic-field we have the production of certain lines of magnetic force, and that currents of electricity produce magnetic-fields. I want now to show you that whenever a conductor is passed through a magnetic-field, work is done upon the conductor, it receives a kind of reaction, currents of electricity are produced. Similarly, if the conductor be placed in the magnetic-field and the current from another source be passed through it, it is urged to move in a certain direction. I am going to show you the instrument itself if I can, but Mr. Carpenter has a similar instrument in the lantern, and the experiment will be repeated before you in another and different form on the screen.

The fact that I want you to understand is, that whenever we pass a current of electricity through a conductor in the neighbourhood of a magnet, or in a magnetic-field, it has a tendency to be moved or to rotate around that field in a definite direction. Here I have a horseshoe magnet; it is surrounded by a cage of copper wire, and through that cage I will cause a current of electricity to flow. You now see that the coils are rattling round at a rapid rate. I take the current off, and they stop; I put the current on again, and away they go. There you have an illustration of the fact that whenever you have a conductor in a magnetic-field, and the conductor is traversed by a current of electricity, it is always urged to move.

I ought to point out to you that here we have the basis of every single experiment I am going to show you to-night. A current of electricity produced rotation, as you saw, in that cage, and in this particular form that I want to show you on the screen you will see that rotation is produced in another way. You now see the apparatus on the screen. On the left and right hand side there are two upright columns, the poles of the magnet, exactly similar to the one I showed you on the table. Between those two poles there is an iron armature rotating on a centre point, and that armature is enveloped at each end by a small coil of copper wire. When a current of electricity passes through that copper wire it magnetises the iron bar, and the iron bar gets attracted and repelled by the two poles of the magnet, so that on my now putting the current on, you see, away it goes. The application of that principle has been carried out in the little apparatus I have here, called Froment's motor. This particular Froment's motor is used to wind a clock; in fact, it has only just been taken from a clock which, at twenty minutes past every hour, was wound up by a current of electricity actuating this motor. By its means the hand-winding of clocks is dispensed with, and, supposing a battery will last for years, so the clock will keep time for years without one being troubled by the necessity of going round the house and winding up the clocks. In order to show you, in a pretty way, one effect of this rotation, I have, through the kindness of Mr. Apps, brought here a motor which works a disc on the front of which some vacuum tubes have been fixed. Here is an induction coil which will produce currents of electricity that pass through these vacuum tubes and illuminate them, and when, by means of the motor, I cause the disc to rotate, you see what beautiful optical effects the persistence of vision produces when you look at electric sparks passing through vacuum tubes filled with a very slight proportion of different gases.

(To be continued.)

EFFECT OF CHLORINE ON THE ELECTROMOTIVE FORCE OF A VOLTAIC COUPLE.*

BY DR. G. GORE, F.R.S.

If the electromotive force of a small voltaic couple of unamalgamated magnesium and platinum in distilled water is balanced through the coil of a moderately sensitive galvanometer of about 100 ohms resistance, by means of that of a small Daniell's cell, plus that of a sufficient number of couples of iron and German silver of a suitable thermo-electric pile (see *Proceedings* Birmingham Philosophical Society, Vol. IV., p. 130), the degree of potential being noted, and sufficiently minute quantities of very dilute chlorine water are then added in succession to the distilled water, the degree of electromotive force of the couple is not affected until a certain definite proportion of chlorine has been added; the potential then suddenly commences to increase, and continues to do so with each further addition within a certain limit. Instead of making the experiment by adding chlorine water, it may be made by gradually diluting a very weak aqueous solution of chlorine.

The minimum proportion of chlorine necessary to cause this sudden change of electromotive force is extremely small; in my experiments it has been one part in 17,000 million parts of water,† or less than one 7,000th part of that required

* Paper read before the Royal Society, May 3, 1888.

† As one part of chlorine in 17,612 millions parts of water had no visible effect, and one in 17,000 millions had a distinct effect, the influence of the difference, or of one part in 500,000 millions, has been detected.

Digitized by Google

to yield a barely perceptible opacity in ten times the bulk of a solution of sal ammoniac by means of nitrate of silver. The quantity of liquid required for acting upon the couple is small, and it would be easy to detect the effect of the above proportion, or of less than one ten thousand millionth part of a grain of chlorine in one-tenth of a cubic centimetre of distilled water by by this process. The same kind of action occurs with other electrolytes but requires larger proportions of dissolved substance.

As the degree of sensitiveness of the method appears extreme, I add the following remarks. The original solution of washed chlorine in distilled water was prepared in a dark place by the usual method from hydrochloric acid and manganic oxide, and was kept in an opaque well-stoppered bottle in the dark. The strength of this liquid was found by means of volumetric analysis with a standard solution of argentic nitrate in the usual manner, the accuracy of the silver solution being proved by means of a known weight of pure chloride of sodium. The chlorine liquid contained 2·3 milligrammes or ·03565 grain of chlorine per cubic centimetre, and was just about three-fourths saturated.

One-tenth of a cubic centimetre of this solution ("No. 1"), or ·003565 grain of chlorine, was added to 9·9 cubic centimetres of distilled water, and mixed. One cubic centimetre of this second liquid ("No. 2"), or ·0003565 grain of chlorine, was added to 99. cubic centimetres of water, and mixed; the resulting liquid ("No. 3") contained ·000003565 grain of chlorine per cubic centimetre. To make the solutions ("No. 4") for exciting the voltaic couple, successive portions of one-tenth or one-twentieth cubic centimetre of "No 3." liquid were added to 900. cubic centimetres of distilled water, and mixed.

I have employed the foregoing method for examining the states and degrees of combination of dissolved substances in electrolytes, and am also investigating its various relations.

THE SUBMARINE TELEGRAPH ACTS.

The following Order in Council was issued on the 3rd inst. :—

WHEREAS by the 2nd Section of "The Submarine Telegraph Act, 1885," it is enacted as follows :—

"The Convention of the fourteenth of March, one thousand eight hundred and eighty-four, mentioned in the schedule to this Act as set forth in that schedule is hereby confirmed and subject to the provisions of this Act the articles of such Convention (referred to in this Act as 'the Convention') shall be of the same force as if they were enacted in the body of this Act:"

And whereas by the 2nd section of "The Submarine Telegraph Act, 1886," which was passed on the 25th of September, 1886, it is enacted as follows :—

"It shall be lawful for Her Majesty in Council at any time after the passing of this Act, to order that the declaration mentioned in the schedule to this Act as set forth in that schedule shall be of the same force, and the same shall accordingly be of the same force, as the Articles of the Convention set forth in the schedule to the Submarine Telegraph Act, 1885:"

And whereas it has been made to appear to Her Majesty that it is expedient to give effect to the declaration set forth in the schedule to "The Submarine Telegraph Act, 1886:"

NOW, THEREFORE, Her Majesty, in exercise of the power vested in Her by the said Submarine Telegraph Act, 1886, and by and with the advice of Her Privy Council, is pleased to order, and doth hereby order, that the said Declaration mentioned in the schedule to that Act, as set forth in that schedule and in the schedule hereto, shall be of the same force as the Articles of the said Convention set forth in the schedule to the said Submarine Telegraph Act, 1885.

C. L. PEEL.

Schedule to the foregoing Order.

SUBMARINE TELEGRAPH DECLARATION.

Certain doubts having been raised as to the meaning of the word "wilfully," used in article two of the Convention of the fourteenth of March, one thousand eight hundred and eighty-four, it is understood that the provision in respect of penal responsibility contained in the said article does not apply to cases of breakage or injury caused accidentally or of necessity in the repair of a cable when all precautions have been taken to avoid such breakage or injury.

It is equally understood that article four of the Convention had no other object, and is to have no other effect, than to empower the competent tribunals of each country to decide in conformity with their laws and according to the circumstances the question of the civil responsibility of the owner of a cable who in laying or repairing his own cable breaks or injures another cable, as well as the consequences of such responsibility if it is recognised as existing.

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, May 11th.

ROYAL INSTITUTION.

9 p.m. Lecture, "Building the New Tay Bridge." By Mr. W. H. BARLOW.

SATURDAY, May 12th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (5). By Mr. C. ARMBRUSTER.

PHYSICAL SOCIETY (LONDON).

3 p.m. Note on "The Condition of Self-Excitement in a Dynamo Machine," and Note on "The Conditions of Self-Regulation in a Constant Potential Dynamo Machine." By Prof. S. P. THOMPSON. Note on "The Electrical Action of Light." By Mrs. W. E. AYRTON. On "The Theory and Practice of Applying the Dynamometer to the Investigation of Transformers." By Mr. T. H. BLAKESLEY. On "Measuring the Electromotive Force of Dynamos and Motors." By Prof. W. E. AYRTON, F.R.S., and Prof. J. PERRY, F.R.S.

MONDAY, May 14th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture VI. "The Decoration and Illustration of Books" (3). By Mr. WALTER CRANE.

TUESDAY, May 15th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be discussed:—"The Tay Viaduct, Dundee." By Mr. PETER CRAWFORD BARLOW, B.A., M.Inst.C.E. "The Construction of the Tay Viaduct, Dundee." By Mr. W. INGLIS, Assoc.M.Inst.C.E. At this meeting the last ballot for members for the present session will take place.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Plant in the War of Nature" (3). By Mr. W. GARDINER, M.A.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "Emigration." By Mr. JAMES RANKIN, M.P.

ENGINEERING SOCIETY (King's College).

4:15 p.m. Paper on "High-Speed Engines." By Mr. LONG.

ROYAL VICTORIA HALL (Waterloo Bridge-road, S.E.).

8 p.m. Lecture, "William Harvey and his great Discovery of the Circulation of the Blood." By Mr. E. A. PARKYN.

WEDNESDAY, May 16th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Electric Lighting from Central Stations." By Mr. R. E. B. CROMPTON. The ATTORNEY-GENERAL, M.P., will preside.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Meeting at the Institution of Civil Engineers. The following papers will be read:—"Report of the Wind Force Committee on Experiments with Anemometers conducted at Hersham." Drawn up by Mr. G. M. WHIPPLE, B.Sc., F.R.Met.Soc., and Mr. W. H. DINES, B.A., F.R.Met.Soc. "On the Measurement of the Increase of Humidity in Rooms by the Emission of Steam from the so-called Bronchitis Kettle." By Mr. WILLIAM MARCET, M.D., F.R.S., President.

THURSDAY, May 17th.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting.

ROYAL SOCIETY.

4:30 p.m. Ordinary Meeting.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Chemical Arts" (6). By Prof. DEWAR, M.A., &c.

FRIDAY, May 18th.

ROYAL INSTITUTION.

9 p.m. Lecture, "La Reproduction Artificielle des Roches Volcaniques." By M. ALPHONSE RENARD.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* THE PROPRIETORS.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
,, Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

CONTENTS OF THE CURRENT NUMBER.

NOTES	1	Anglo-American Telegraph Co. (Limited) *v.* La Compagnie Française du Télégraphe de Paris à New York	20

VOLUME XX. OF "THE ELECTRICIAN"

READY NEXT WEEK. Bound in cloth, price Ten Shillings and Sixpence. Also Cases for Binding, price Two Shillings.

Applications should be made to "The Publisher."

INDEX TO VOLUME XX.

With this number a Supplement is issued (Gratis), containing the Index to Volume XX. This Supplement should be received with every copy of the paper. Complaints of non-receipt should be at once forwarded to the Publisher.

THE PORTRAIT OF SIR JOHN PENDER.

To meet the desire of those who wish to frame the Steel Plate Portrait of SIR JOHN PENDER, given with our issue of the 27th April, a limited number of impressions have been taken on large paper, and can be obtained in a neat black and gold or carved brown frame, price Four Shillings each.

Orders to be addressed to—
The PUBLISHER,
"Electrician" Office, 1, Salisbury-court,
Fleet-Street, London, E.C.

TELEPHONE AMALGAMATION.

If the first effect of the POSTMASTER-GENERAL'S declared intentions with regard to the Telephone Companies was to inspire some rather precipitate exultation, the effect of his later pronouncement has been to provoke some perhaps unreasonable resentment. Whatever may be the wishes of the managers of these companies, there can be little doubt that the feelings of the shareholders, as indicated on the market, were favourable to a Government purchase. And when subsequently Mr. RAIKES let it be known more explicitly what his policy really was, namely, to allow the business to go on until he could buy it, if so disposed, at an advantage, the fall in the value of telephone stock and the openly-expressed opinions of the financial press betrayed pretty plainly the angry disappointment it occasioned. It is no doubt in obedience to this sentiment that the companies have approached each other with a view to determine what measures of self-defence it will be wise for them to take. Some counterstroke of policy was in the first heat of the moment suggested in certain quarters; but as we pointed out at the time, any retaliatory measures would probably only result in exasperating the public, and would be really playing into the POSTMASTER-

Digitized by Google

GENERAL'S hands. More reasonable councils we are glad to notice have prevailed, and what is now proposed to be done is no more than the companies are perfectly justified in doing in their own interests, and certainly not more than Mr. RAIKES might have anticipated they would do. Negotiations have already made some progress for the amalgamation of the companies; and in a few days' time a meeting of representatives of metropolitan and provincial telephone systems will be held in London, at which some definite resolution may probably be formulated.

Assuming that the POSTMASTER GENERAL will not interpose any obstacle in the way of this union—and we have no reason to suppose that he has either the wish or the power to do so—there is very little doubt that the companies will come to a satisfactory arrangement among themselves. Some outlines of the terms have been already foreshadowed in the press; but we have reason to believe that they have no official authority, and that in some particulars they are erroneous. We may, however, leave these matters to the parties whose interests are so closely bound up that a friendly settlement among them may be confidently predicted. That a working agreement of some kind would have to be entered upon has long been evident; and Mr. RAIKES' latest announcement has only had the effect of precipitating matters a little. With the object of strengthening their position in view of eventualities not far distant, the companies must have come together before very long; and the rapid development of long-distance telephony has rendered this step imperatively needful without any further delay. The rise and progress of this branch of their business has been almost as much a surprise as the rise and progress of telephony itself. Telephony, as originally designed, was merely what may be called a superior kind of speaking tube, far more flexible it is true, and of longer range, but still only local, urban and domestic in its application. It has grown to be not only something more than this, but something quite different. Besides serving the modest uses for which it was at first designed, though on a wider scale than had been imagined, the area of its operations has been immensely extended, and it is now to all intents and purposes a telegraph worked by telephony.

We revert to this important change in its character, because the fact that it was unforeseen explains the present situation better than anything else can. If this remarkable transformation had been anticipated, it is at least possible, and we think not improbable, that the Post Office would have been less willing to issue licenses to companies who are now its competitors for telegraphic business. And it is equally probable that the United Telephone Company, which may be called the parent of the provincial companies, would have acted somewhat differently also in the granting of their licenses. As matters stand, the country is cut up into various districts of unequal dimensions, and of greatly dissimilar service, some parts being very well serviced, others not so well, and some still not opened up at all; but the commercially-paying districts are pretty thoroughly covered, and within itself each one has its trunk lines in tolerably complete intercommunication. Some of these districts have gone a step further, and are connected one with the other, so that their customers have the advantage of speaking often far beyond the limits of the system to which they subscribe. To what extent this has been done already, and to what it is capable of, the information published in these pages recently has sufficiently testified.

Now it is obvious that all this is tending towards union in some form or other, and that it cannot long be delayed. The streams, since they have acquired strength by combining, are fast flowing towards London; and it is not possible for the parent company to hinder, even if it were inclined to do so, the strong desire to connect all the provincial systems through to the metropolis. By the time this is accomplished the several areas will probably every one of them be connected with each other, and consequently London with them all. This result, indeed, has been inevitable ever since the practicability of long-distance telephony was proved, and its practice taken up by the companies as part of their business. The local areas assigned under licenses could no more be kept separate and isolated than could a telegraph system under similar conditions. That the people of Derby may telephone to Nottingham, but not to Leeds, would be as absurd as to impose a like artificial restriction on the telegraph. Once admit that telephonic telegraphy is a business in which the telephone companies may legitimately engage, the public whom they are permitted and required to serve have a right to demand that it shall be universal. And for this reason, if for no other, we do not apprehend the least opposition on the part of the public to the proposed amalgamation of the companies. As there is no competition under the present arrangement, no reasonable exception can be taken to the creation of a big monopoly. Monopoly has been described as the slaughter of the prisoners when contrasted with competition which is civil war. But seeing that the State has elected to waive its rights to assume the monopoly of the telephonic branch of its telegraph business, neither the State nor the public has any cause to be alarmed by the companies combining to further their own interests. The State will still exercise a controlling influence over the monopoly; and perhaps it is better to have a semi-independent monopoly, efficiently regulated by the State—as was argued in connection with the proposed State purchase of the railways the other evening—than to augment the monopolies already owned by the State. Practically, if not avowedly, this is the attitude at present taken up by the Postmaster-General; and it rests very much with the Telephone Companies what their future will be.

OBITUARY.

SIR CHARLES BRIGHT, F.R.A.S., F.G.S., M. Inst. C.E.

It is with profound regret that we have to announce the sudden death of Sir Charles Bright, which took place at his residence, 78, Philbeach-gardens, on Thursday, the 3rd inst.

Charles Tilston Bright was born in 1832. His father, Mr. Brailsford Bright, represented the elder branch of an old Yorkshire stock, long settled in Hallamshire, a district near Sheffield. Sir Charles Tilston was the youngest son, and had several brothers. He first became connected with electro-telegraphy in 1847. In 1852 he became engineer to the Magnetic Telegraph Company, in which capacity he took part in the submersion of the first submarine telegraph cable between Great Britain and Ireland, from Port Patrick to Donaghadee, in 1853. He held this appointment for eight years—during which period the greater part of the company's lines were constructed under his superintendence—and in 1860 became their consulting engineer, a post which he held until the land telegraphs were taken over by the Government in 1870. In 1854 he engaged in an extended series of experiments upon the retardation experienced in subterranean and submarine conductors, and in the following year entered into a partnership with Messrs. Cyrus Field, John Watkins Brett, and Dr. Whitehouse, with a view of forming a company to lay a submarine cable across the Atlantic; having satisfied himself and them of the feasibility of working through so long a distance without the signals becoming blended together, a fact which, strange as it may seem to us now, was disbelieved by many at that date. In 1856 the time was considered ripe for putting the great project

Digitized by Google

into a practical shape, the lines of the Magnetic Company being extended to the West of Ireland, and those of the New York and Newfoundland Company (of which Mr. Field was vice-president) being laid to Newfoundland. A company was accordingly formed, with 350 shares of £1,000 each, the subscribers being principally shareholders in the Magnetic Telegraph Company, among whom Sir Charles Bright was the first to enter his name for part of the capital. Mr. Brett became one of the directors of the company, Sir Charles Bright the engineer, Mr. Cyrus Field the manager, and Dr. Whitehouse the electrician. The cable was laid successfully in 1858, the end being landed by Sir Charles Bright in Valentia Bay on the 5th of August in that year. For this national service he received the honour of knighthood. In 1860 he laid a series of cables for the Spanish Government from Barcelona to Minorca, Majorca, Iviza, and back to Cape San Antonio on the mainland. In 1861 he entered into partnership with Mr. Latimer Clark, as the firm of Bright and Clark. He afterwards, in 1864, laid the first working cable to India, for the Government of India, from the head of the Persian Gulf to Kurrachee, a distance of nearly 1,600 miles. Sir Charles Bright was returned to Parliament as member for Greenwich in 1865, and sat until the election at the end of 1868, when he retired, being engaged in the Gulf of Florida laying a cable from the United States to Cuba, and his seat was transferred to Mr. Gladstone. While Sir Charles Bright was in Parliament he took an active part on the East India Communications Committee, part of the outcome of which was the formation of the Eastern Telegraph Company a few years later. In 1869 he was engineer to the Anglo-Mediterranean Company, by which a direct line was laid from Malta to Alexandria. In the following year he was joint engineer to the Falmouth, Gibraltar, and Malta Company, the Eastern Extension Company from India to Singapore, and to several other companies. In this and succeeding years he laid many cables between North, Central, and South America, connecting Cuba, Porto Rico, Jamaica, St. Thomas, St. Kitts, Antigua, Guadeloupe, Martinique, Dominica, St. Lucia, Barbadoes, St. Vincent, Grenada, Trinidad, Demerara, and Panama. In 1881 he was appointed by Her Majesty's Government as one of the British Commissioners to the French Electrical Exhibition. Sir Charles Bright was the inventor of many important improvements in telegraph apparatus, and the manufacture and laying of submarine cables, which are extensively used. He was a Past President of the Society of Telegraph-Engineers and Electricians, a member of the Institution of Civil Engineers, of which he was the Telford gold medallist in 1864, and a Fellow of various other learned societies, as well as an officer of the Legion of Honour.

The funeral took place on Monday last at Chiswick, the first part of the service being held at St. Cuthbert's Church, opposite Sir Charles's residence, and was attended by a large number of personal friends and professional men engaged in telegraph and submarine cable enterprise, with which Sir Charles Bright's name will always be honourably associated. Amongst those present were the following:—H.S.H. Prince Victor Hohenlohe-Schillingsfurst; Sir Francis Burdett, Bart.; Sir R. Jardine, Bart., M.P.; Sir W. Thomson, F.R.S.; Sir S. Canning, M.I.C.E.; Major-General Sir Frederick Goldsmid, C.B., K.C.S.I.; Mr. Edward Graves, President S.T.E. and E.; Mr. Latimer Clark, Past President S.T.E. and E.; Prof. Hughes, F.R.S., Past President S.T.E. and E.; Mr. Preece, F.R.S., Past President S.T.E. and E.; Mr. Benest, Mr. R. Collett, Mr. Clifford, Mr. H. C. Forde, Mr. R. K. Gray, Mr. John Muirhead, Mr. E. Stallibrass, Mr. E. March Webb, Mr. F. C. Webb, Mr. F. H. Webb. Many others were prevented by pressing engagements from attending. Sir D. Salomons's carriage was amongst those which followed in the *cortége*, Sir David being, much to his regret, unable to attend.

Dr. Werner Siemens.—The Berlin official *Gazette* publishes a list of the personal honours with which the Emperor Frederick has marked the opening of his reign. Among those who have been ennobled or dignified with the prefix "Von" are Prof. Gneist and Dr. Werner Siemens.

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

MONDAY, MAY 7TH.

The examination-in-chief of Prof. SILVANUS THOMSON was continued by Mr. FINLAY as follows:—

Have you anything further to say about exhibits J H 2 and J H 3?—I was about to say I could see no difference between J H 2 and J H 3, and I think I was further going to add that the joints appear to be made in a different manner from anything contemplated in Edison's specification.

Would you look at the series of exhibits marked I T, made by Mr. Gimingham?—I T 1 has a conductor made on a spiral, and the coils of the spiral are so open that they could not fulfil the requirement of offering only a small radiating surface. There is no appearance on the platinum wires indicating that they have been subjected to the process of carbonisation. The platinum wires attached to the carbon are not mounted to other platinum wires by clamps, and they are supported just below the joints by a little piece or disc of glass in the manner described in specification 539 of 1881. The wires themselves are sealed through the lower end of the bulb, after the manner described in specification 4,174 of 1881. The conductor in this case, as nearly as I can measure it from the outside, is 26-thousandths of an inch thick. There is considerable discoloration of the lower part of the bulb, which I should think is due to the incomplete driving off of the tar in the cemented joints or in the conductor itself.

[The witness proceeded to point out similar discrepancies in the other lamps of the series.]

Take the other exhibits produced by Mr. Gimingham marked E G 1 and following numbers?—E G 1 has a conductor looped but not coiled, there are no internal clamps, the bulb appears to be separately blown and joined on afterwards, and there is a yellow discoloration.

What about E G 2?—E G 2 has a coil of three turns wide apart from one another; there is an internal support of glass just below the mounting. The platinum wires show no trace of having been in the carbonising pot. The wires themselves are sealed direct to the lower end of the bulb, and the conductor is about 23-thousandths of an inch thick, or No. 24 Birmingham wire gauge.

Take E G 3?—E G 3 has a conductor that does not visibly vibrate when tapped. The bulb appears to have been separately joined on, and there is no appearance of the wires having been in the carbonising chamber. The conductor appears to be about 27 Birmingham wire gauge, or 16-thousandths of an inch.

Similar evidence was given with regard to the remaining lamps of the series.

With regard to these lamps of Mr. Gimingham's, are you able to say from your examination of them whether they would be commercial lamps?—I doubt if they would be durable lamps.

Take the two specimens produced by Mr. Crookes of filaments coated with non-carbonisable substances, marked W C 9 and 10, what do you say about them?—W C 9 is a lamp which was made at Mr. Crookes's, and it was tested in my presence.

The ATTORNEY-GENERAL: Did you see it made?—I saw the conclusion of the making process, and a portion of the operation of making. It was tested while still on the pump in my presence, and I saw the reaction taking place which ended in the destruction of the lamp.

There is one other exhibit produced by Mr. Crookes—W C 23—said to be Edison's bamboo lamp?—I think I have already seen this lamp, and it is not bamboo at all.

What do you say it is in your judgment?—Whatever it is it has been subjected to some process. Its surface is white and metallic, and it is not mounted in the way Edison's lamps are mounted at all.

How does it differ from them in the mode of mounting?—Every lamp that I have ever seen put into the market as an Edison lamp with bamboo conductor this differs from in several respects. The joining is made in a different way, the platinum wires are in one piece; in fact, it does not possess any of the peculiarities which I pointed out as characteristic of Edison's lamp so largely introduced about the year 1882. I never saw that lamp before this trial; it might have been made for the purpose.

Did you examine the filaments of tar putty put in during the cross-examination by the Attorney-General to Mr. Crookes?—Yes, I have examined these filaments.

What do you say about them?—A, B and C are about 40 or 41 thousandths of an inch thick. They are not quite uniform, though nearly so, but they exhibit a number of small cracks. The filament marked D is about half as thick, and is not so uniform; it is thinner in some places than in others. There is a spiral a good deal thicker than in any of the others, and it has been carbonised; it also presents inequalities in diameter.

Have you tried yourself to make tar putty filaments?—Yes, I have several times.

Have you got any specimens here of your work?—Yes. [Specimens produced.] I made these last Wednesday; that is the third occasion on which I have tried such experiments. Four years ago I tried tar putty on slate, and gave it up as an entirely hopeless job. The second occasion was at Mr. Crookes's, where I employed part of the same mixture which he was using, lampblack which had been in a crucible for some hours, mixed with tar and rolled out. The best results I got then were not so good as those I have here. The third time was last Wednesday evening, the results of which I have got here. I took lampblack, such as already was existing in my laboratory, and sent out for some tar, and having ignited the lampblack in the crucible, first of all for half an hour and then for three hours, I tried to roll out these strings of putty. I tried to roll them on a plate, on the palm of my hand, and on a porcelain plate, on a

Digitized by Google

plate of glass, on paper, and, last of all, upon rather coarse pieces of cardboard. And the best results were got by rolling the stuff upon a clean piece of cardboard, using another clean piece of cardboard to roll it out. I consider the tar putty process, as a whole, quite an impracticable one for commercial use, on account of the contracting that goes on, and the liability to distortion and fracture. And the addition of camphor is simply fatal to the working process. I would only add, every one of those specimens I have had was complete when I laid it out on a sheet of paper, and of these two broke while the paper was resting on a rigid pedestal.

Were you present at the experiments made by Mr. Crookes with regard to infusible bodies, non-conductors of electricity, or non-conducting non-carbonisable substances?—I was present when they were coating some of those tar putty filaments with fireclay and trying them, and I also saw the results of burning lamps, the conductors of which had been coated with some other materials than fireclay.

You have heard the evidence given already on this point by Mr. Crookes?—I have.

Do you agree with it?—Entirely.

Is there anything you have to add?—Yes; that those lamps I saw tried were sealed to the pump when they were being tried, and that they were sealed by passing a current through them, first gently, then more strongly, and that I observed no depreciation in the gauge of the pump indicating that gases were being given off until the conductors had been raised to a full yellow heat; also that before the conductors had been raised to that degree the brilliancy and whiteness which is ordinary in running lamps before any arc has been formed at any part of the conductor gases began to be given off, producing a well-marked depression in the mercury of the gauge pump. It fell without doubt, and at the same time the bulb was more or less filled with faint glow, and portions of the conductor became by themselves more highly luminous. It was at this stage that the spectroscope showed lines indicating volatilisation, and of course the reduction of the materials of the non-carbonisable coating. The added materials did not require to be kept up to the same stage of incandescence before the phenomena took place; but every one of them I saw was in this way volatilised and destroyed long before they had been heated up to the ordinary degree of an incandescent lamp.

You have examined Mr. Cheesborough's specification?—Yes.

I would ask you what you have to say as to what is stated at page 15, line 49, regarding infusible substances, non-conductors of electricity—a tube of lime enclosing a pencil of carbon, through which a current is passed?—I witnessed the experiments made by Mr. Crookes, and I agree with him.

Have you examined the Paper by M. Deprez?—I have.

And have you also examined Sidot's papers?—Yes.

What do you say as to the substances yielded by Deprez, the Sidot process as compared with the substances in Cheesborough's process?—I regard the substances yielded by Cheesborough's process as absolutely identical with the substances which were produced by Deprez and Sidot processes.

So much with regard to the substances; have you compared the processes themselves?—Yes, I have. The processes themselves appear to me to be mere variations in detail of the same process, viz., that of heating, by means of an electrical current, a conductor, which becoming incandescent at the surface acts upon the surrounding fluid containing carbon, and dissociates the carbon from it, becoming coated thereby. In that sense Cheesborough has struck out of his first specifications the only two hydro-carbons that he ran.

With regard to the material yielded by the various processes, what do you say?—The material yielded by Sidot's process is the same as that yielded by Cheesborough or by Deprez.

How does the process differ?—The physical action is the same, *i.e.*, there is decomposition of the surrounding fluid containing carbon resulting from the contact of the surrounding fluid with a highly-incandescent surface. So far as the material is concerned the reaction is solely and purely consequent upon the high temperature of the surface that is brought into contact with the carbon or liquid containing gas.

Cross-examined by Mr. MOULTON, Q.C.: You say with reference to the processes of Sidot and Deprez that so far as substances are concerned they are the same. Do you say that Cheesborough's conductors could be got by Sidot's process?—What I said was the material was the same.

Do you say that the conductors described in the Cheesborough's specification could be obtained by Sidot's process?—Some of them may not.

Could any of them be so obtained?—Yes, I think so.

Please understand me. Can they be obtained as conductors of the same regularity as by Cheesborough's process?—The carbon would be deposited in perfectly regular layers wherever the incandescent surface was in contact with the gas.

I ask you whether you could obtain these conductors with the same regularity in them as by Cheesborough's process?—Do you refer to regularity of form or regularity of material?

I talk about regularity in everything.—Well, I can only talk about it in two stages. So far as regularity of material is concerned, I think the two processes would produce exactly the same results. With regard to regularity of form, I do not think that Sidot's process would, without modification, produce as great a uniformity of form as Cheesborough's.

In making electric conductors, regularity of material and form are both important, are they not?—They are not necessarily. Regularity of material and form are not respectively important for a lamp conductor. My reason for saying that is that in modern lamps the process of flashing does not produce uniformity of diameter.

What is important, I understand, is uniformity of electrical resistance?—No, not even that.

Will you kindly tell his lordship what is important?—It is of importance that the conductor should be so built or so shaped as to glow at every point of its surface with an equal degree of incandescence.

Do you suggest you would get that by Sidot's process?—By a modification of Sidot.

Do you suggest you could get that by Sidot?—No, not by Sidot alone.

Is it not a fact that you can get that by Cheesborough and by no other process that is known?—I do not know that.

First of all, can it be got by Cheesborough?—By applying a portion of Cheesborough's patent.

Then it can be obtained by Cheesborough, but Cheesborough gives you some other method?—Cheesborough does not tell you how to do it.

But, by the process Cheesborough describes it can be done?—Oh, yes.

I put it to you that by no other known process can it be done. Is that so?—Oh, no.

Tell me all the known processes by which it can be done?—I think I can do so. Specification 562 of 1881.

Did you ever try that?—No, I never tried that, nor Cheesborough's either.

Can you say of your own knowledge whether this would succeed?—It would certainly deposit carbon. It is a question of care, time, and patience.

Do you suggest that this would make the carbons glow uniformly throughout, as Cheesborough's will?—Undoubtedly, if properly applied.

You say so in practice?—I have no doubt, though it is not in practice yet.

Have you ever heard of a single lamp being made in this way?—No.

This would not do it automatically, would it?—I think not.

Have you any doubt about it?

Mr. JUSTICE KAY: That depends on what you mean by automatically.

Mr. MOULTON: I mean if it would find out the weak places for itself?

Witness: Certainly not.

Would there be anything automatic in the connection?—I think so.

It not only finds out the weak spot, but the connection is proportional to the weakness?—Undoubtedly.

Any defect in the inside which you suggest should be remedied?—I do not think either process corrects the inside satisfactorily.

You have never tried Cheesborough, and you do not know whether it affects the interior or not?—I have seen the process.

But you have never examined to see whether Cheesborough does affect the interior?—No; I have never seen that.

Supposing Sidot's filaments formed of little balls touching one another, would that be regularity suitable for a conductor?—Not at all.

I understand you to say that the Deprez and Cheesborough processes are merely variations of the same process?—Cheesborough is a variation of Deprez.

In the first place, how do you suppose Deprez placed his carbons?—Between two clamps in some cases.

And, how with regard to the electric current?—So that the electric current would go through them.

Where do you get that?—All through the description.

That is your interpretation of the Paper?—Yes.

We know what the objects of these experiments were, they were the fusion and volatilisation of carbon?—That was the title of the Paper.

In every one of these experiments did not he get either fusion, volatilisation or rupture of carbon?—I think in almost every case he claimed something of the kind.

This being the uniform result of his experiments, when he comes to experiment in hydro-carbon he does not say the result is different, excepting so far as there was a deposit besides?—It is utterly unsuitable for softening.

He calls attention to difference in the result. Is there any portion which calls attention to any difference in the effect so far as fusion and ruptures are concerned?—He does not even mention fusion or rupture.

But in all the other experiments he mentions one or the other?—Yes.

Have you tried the experiment of putting this enormous current through a hydro-carbon rod?—He was only dealing with small currents.

I am asking you if you tried the passing of these enormous currents through the carbon?—Certainly not.

I understand you to say that taking into consideration the size of the carbon conductor the currents which Deprez used were not enormous?—I should not think they were.

Do you remember Mr. Preece giving a lecture at the Society of Arts on the electric lighting at the Paris Exhibition?—I do not think I was there; but I may have read it afterwards.

I think you take *The Electrician*?—Yes.

Did you read the lecture in that journal?—Probably I did.

Were you on the jury of the Paris Exhibition?—No.

Mr. Preece, in his lecture, says, "There were several incandescent lamps; that which possessed the greatest novelty and was decidedly the most efficient was that of Edison. Its distinctive character was the remarkable uniformity of its texture and light-giving powers." Are you prepared to say that is not a correct description of what was shown in Edison's exhibit?—Contrasting them, I should differ in detail from the description of the lamp. I should entirely doubt the right to use the word efficiency, because my recollection is that the lamps were not so efficient as some of the other lamps shown at the Exhibition. As to their being a novelty, I think that is right, for nobody had seen them before that day.

You are not prepared to say that the Edison lamp was not the most efficient?—I am, judging by the way in which these lamps themselves were then shown. Doubtless the owners did not wish to burn them brightly; my inference from that was that they might break down.

The Electrician, in a description of the electric lighting apparatus, 22nd October, 1881, says, "The lamps numbered 160, and two rooms were lighted with Edison's exhibits." Is not that a correct description?—Yes, that is correct.

Then I put it to you, were there 160 lamps?—I cannot say.

Digitized by Google

Did you take any notice of them?—I do not think I took any particular notice. I am speaking from general recollection.

This was published 22nd October, 1881; are you prepared to say it was incorrect?—No, I am not prepared to say so, I did not see the lamps. I remember seeing a number of Swan's festooned all round the hall, and they made a great impression. I felt disappointed at seeing so few lamps lighting Edison's show cases.

Was it the small number of lamps that struck you?—Yes, and the lower degree of incandescence at which they were running. The lights were much redder.

You have been asked several questions about a lamp put in of the Edison type—W C 23; will you kindly tell me what difference there was between what you saw at Paris and W C 23?—My recollection of the Paris lamps is that they were like that produced by Prof Frankland, E F I, and not like this.

Leaving out the question of attachment of the carbon conductors to the wires, do you say that either of these is not made in accordance with Edison's specification?—It is made in accordance with a number of subsequent specifications. It is not made in accordance with Edison's specifications.

Is there a carbon filament in E F 1?—Yes.

Within a receiver made entirely of glass?—Yes.

Through which the leading wires pass?—Yes.

And from which receiver the air is exhausted?—I have no doubt of it.

Take now W C 23, and answer the same question?—Yes.

Do you say that C F 1 is not made according to Edison's specification?—It is not.

Is not the conductor there of fibres made of vegetable substances?—I have no doubt it was.

Which would leave a carbon residue after heating in a close chamber?—That would depend.

Do you suppose it has been heated in a close chamber?—I think it has.

Mr. JUSTICE KAY: This is all argument.

Mr. MOULTON next referred to "Chambers's Encyclopædia" for certain definitions, and asked witness if it was a rare or unrecognised book?

Witness: I do not happen to possess it.

You have heard of people doing so?—I have.

I have a copy here dated 1851, and in an article on carbon it is said "carbon was used for electrical purposes, mainly referring to Bunsen's carbonisation for batteries." They were well known, were they not?—Oh, yes.

Do you know how these were made?—I know the process in general.

After what I have read from "Chambers's Encyclopædia" do you tell his lordship that it was not well known that in carbonising charcoal, if you did not wish them destroyed, you packed them with charcoal dust?—All I can say is that it was not known to me.

Mr. JUSTICE KAY: He says that it was not known to him, and the inference would be that it would not be known to an ordinary workman. That is all this evidence goes to show.

Mr. MOULTON (to witness): Do you know a common manual called "Brand and Taylor's Chemistry," published in 1863?—I do. I have read it. I have referred to it, but not often,

In it there is a passage: "Charcoal may be obtained from either vegetable or animal substances. In order to procure it it is necessary that the organic matter should be heated to a high temperature out of contact with air."—I did not know that. I never read that passage. I knew it could be made that way.

But did you know that in order to procure charcoal it is necessary that the organic matter should be heated to a high temperature out of contact with air?—I knew that carbonising was a process of imperfect combustion.

Can you find me any book or treatise in which carbonisation is said to be a process of imperfect combustion?—I do not recollect. When heated in the chamber I call this destructive distillation.

Do you think that was what was referred to by whatever it may be called, in the phrase "having fibrous vegetable substances after heating in a close chamber"? Do you suppose that what I have been talking about was what you call destructive distillation?—I am not sure. It looks very like it.

If it was destructive distillation you would keep the air from contact with the organic body?—Yes; as far as possible.

[Shown lamp G I 3.] You said that was a machine-made bulb?—I said my impression was that it was a machine-made bulb.

What has that got to do with it?

Mr. JUSTICE KAY: I understood witness to mean that it was not blown over the hole, but was made separately by machinery and then attached?—Witness: Yes.

Mr. MOULTON: (To witness). Do you suggest that it makes any difference whatever as to whether it is blown before or after, whether it is ready made or blown out afterwards?—I suggest it is a different process of manufacture, and it would be a very difficult thing, commercially, to try and blow a bulb over such an arrangement as this.

What meaning do you attach to the words to have a "bulb blown over it"?—That you put it there and blow it.

May I ask whether your knowledge of glass blowing is extensive?—I have seen bulbs blown many times.

In glass blowing you have a little blob of glass; you blow into that and it will expand into a bulb?—That is one way. The other way is to take a piece of glass tube hot on a blow pipe, and then blow it so that the tube expands. I supposed it was one or other of these two methods which was meant.

How would the second method differ from the statement of the specification?—The process is completely different. I would not have thought it worth mentioning if Mr. Edison had not used these words.

You do not mean to say that the glass being blown over it would make any difference?—On the contrary, there would be a difference. It would be a great source of trouble.

Would any practical person have any difficulty in understanding what was meant by the glass globe being blown over it?—I think they would take it that the globe was to be blown over the filament.

Mr. JUSTICE KAY: You think it would be much more difficult than making the bulb separately?—Yes.

Mr. MOULTON: Do you suggest that there would be the least difficulty in understanding what Mr. Edison meant?—No, I think not. I think it was clear. He meant it was to be blown over, and not to be blown from the thing; that he was not to put the filament in the tube, and by blowing expand the tube.

You do not suggest that while blowing it into a bulb you had the filament inside?—Certainly.

Mr. JUSTICE KAY: Really all this is a matter of construction; whether material or not is quite another matter.

Mr. MOULTON: You have called attention to the descriptions of Mr. Edison in his specification of the then state of electric lighting by incandescence, and you say they were incorrect, because of the three specifications of Mr. Lane-Fox, among other things?—I think I referred to them.

You never knew of any lamp being made in accordance with these three specifications, did you?—They were made; they were not sold.

Did you know of one made before 1879?—I think I did.

Are you prepared to swear you did?—I think I saw some.

Are you prepared to swear you saw them before the date of Edison's patent?—I cannot tell you the date.

Mr. JUSTICE KAY: Is it not admitted that the lamp F G B 1 was made before the patent?

Mr MOULTON: Yes.

Mr. JUSTICE KAY: And this does not accurately describe the Swan lamp?

Mr. MOULTON: No.

Mr. JUSTICE KAY: It has been admitted frankly that Edison did not describe the actual knowledge at that time. As to what you said as to Sidot's light. Can you tell me of a single installation on Sidot's principle of incandescence?—Yes, at Wittlesborough. I think that was on that principle. I will not swear it.

With regard to the lamps that were made with carbon and not carbonisable material, I understood your evidence in regard to that was that these were heated to full yellow incandescence. Your view is that you had got to the temperature at which carbon would unite with non-carbonisable substances?—At that pressure. We had got to that temperature at which the carbon would unite with the oxygen and non-carbonisable matter.

That must necessarily be the limit of the temperature which such a lamp, composed of whatever substance it was, could stand?—Yes, it must be.

Mr. JUSTICE KAY: And did they give light?—They were not heated to the height that they should have been had they been commercial lamps. Destruction took place before that heat was arrived at.

Mr. MOULTON: Had they been carbon lamps you could have raised them to a much higher incandescence?—If purely carbon lamps undoubtedly.

As to the filaments which were made, look at E F 2. How do you suggest these were made?—I do not know.

Take W C 25; you say you never saw such an Edison lamp before, and that it is not bamboo. How do you say that?—Because it is quite different in appearance; it looks like twisted thread.

Are you prepared to say the original filament is not bamboo?—I do not think it is.

Prof. JOHN PERRY, examined by Mr. GRAHAM, deposed as follows: I remember a meeting of the Telegraph Engineers, at the Institute of Civil Engineers, November, 1880. Swan's lamps were exhibited there. They were incandescent lamps, very much like the lamps in use at the present day. There were twelve lamps. On that occasion Mr. Swan delivered a lecture about his former experiences. Going to the British Association meeting, in August, 1881, at York, I remember Swan's lamps being exhibited, lighting up the picture gallery. I made a number of measurements of the efficiency of Swan's lamp in May, 1881. I believe Prof. Ayrton and myself were the first to measure the efficiency of the lamps. Compared with the best lamps now known, the Swan lamps in 1881 were exceedingly good in respect of efficiency. Again, I measured the efficiency of the Swan and Maxim lamps in October, 1881. Those measurements were made at Finsbury Technical College, with Prof. Ayrton. At that time we obtained very much higher electrical efficiency from lamps than is ever obtained now from incandescent lamps in regular working, because at that time it was not sufficiently well known that lamps may be made to give out too much light for their lives. Now with regard to the lamps exhibited by Mr. Swan to the Society of Telegraph-Engineers, I am in a position to say, from their bright appearance, that they must have been burning with much the same efficiency as lamps of the present day. They burned for several hours. Those lamps exhibited by Mr. Swan must have undergone a considerable amount of testing before he would have dared to exhibit them on such an occasion. I remember the auditorium of the Savoy Theatre being lighted in 1881 with over a thousand Swan lamps. At the Paris Exhibition of 1881 the Swan lamps had the appearance which lamps now generally have, the Edison lamp had a reddish orange appearance, and from my knowledge I should say it was burning very inefficiently. A Gramme dynamo was shown at the British Association meeting in 1874, when I explained its construction to many electricians. Before that time electricians in this country were almost ignorant of its construction I have heard the evidence of Prof. Thompson about the advantage of high resistance, and I agree with him. I have seen F I B 1—the Swan lamp put in by Sir Frederick Bramwell. Having regard to the sort of dynamos in existence in 1879, I think you

Digitized by Google

have there nearly the minimum thickness for dynamos at that time, taking into account that running with pumps was unknown. I think it was very much better able to resist shocks than anything which could have been made under Edison's patent. Going to Cheeseborough's specification, he probably was using a producer of electrical force, and, in that case the current would automatically increase, the temperature would slightly increase if left to itself, unless the battery was frightfully bad. If you use a dynamo machine the temperature would certainly increase, and it would be necessary to adopt some means for increasing rather than diminishing the resistance. When the section increases two per cent. the current has only to be increased one per cent. to keep it at the same temperature. It is not necessary to make any provision for increasing the current when using the dynamo. The total output from the 600 cells—the largest battery used by Deprez—was probably considerably less than half a horse-power. And that is exceedingly small.

Cross-examined by the ATTORNEY-GENERAL: Swan certainly had much the better of Edison at the Paris Exhibition in 1881.

If you had been asked to describe the Swan lamp would you not have said it was a vessel of glass, platinum leading-wires, a filament of carbon, and a complete vacuum?—Certainly not. He used the same combination in 1878.

Will you kindly tell us what you say was the novelty of the Swan lamp as exhibited in 1881?—That he had manufactured them in exceedingly large numbers and had made a great commercial success.

Any other novelty?—No; I do not know of any other.

Look at that lamp [handing up lamp], does that not represent Swan's lamp of to-day? It comes, I may say, from Her Majesty's Royal Courts of Justice?—Yes.

Speaking of its leading features, does it not consist of a vessel of glass, leading-wires sealed in it, and a carbon filament, the vessel being exhausted?—Yes, I think so.

Sir HORACE DAVEY applied for leave to have the examination of Mr. Carré taken in Paris, as he was unable to attend the court in England and give evidence through an interpreter.

The ATTORNEY-GENERAL asked for evidence of the inability of the witness to attend.

It was agreed to delay the matter, and the Court adjourned at four o'clock.

TUESDAY, MAY 8TH.

Sir HORACE DAVEY: I mentioned yesterday afternoon that we were disappointed in believing that M. Carré, as he led us to believe, would be here to give evidence before your lordship, and the application I have to make is that he should he examined in Paris. We wish to prove that he made his carbons; that those produced were made by him; if necessary, the mode in which he made them, and probably if they were received in that particular shape for carbonisation. Secondly, we wish to prove that he sold similar carbons which had received that shape before they were carbonised, after they had been made into those rods or pencils, and that he supplied those to Swan before November, 1879. I should also, if he had been here, have asked him to look at the carbon in the Swan lamp, and say whether that was one of those carbons he had supplied to Mr. Swan. I regret that the affidavit which was sworn is not in court; it appears to have gone astray between two gentlemen, and has been mislaid. Directly before it was sworn, General Webber, manager of one of the departments, saw M. Carré in Paris, and was told by that gentleman that it was not convenient for him to come to England. Under these circumstances, we ask your lordship to allow him to be examined on Friday or Saturday in Paris.

The ATTORNEY-GENERAL: I wish to facilitate matters as far as I possibly can, and I asked your lordship last night to allow my learned friend to point out the grounds on which he was going to make this application, because it is impossible, unless we have something definite, that this application can be acceded to. Of course it is important to avoid expense. The granting of this application means sending over to Paris Mr. Moulton and a skilled chemist. So far as Sir Horace Davey has indicated what M. Carré will prove, and in regard to the fact that the lamp F I B 1 has a carbon made by M. Carré, I admit that at once. And I should think it makes no difference to my purpose that somebody may have had more pieces like that in the lamp than the one in the lamp itself. I am quite prepared to consent that he got indirectly from Carré the carbon which is in the lamp F I B 1, and I admit, if it must be so, that it was made by Carré's process.

Mr. JUSTICE KAY: It may be material to prove that M. Carré's carbon was formed in that shape before being carbonised.

The ATTORNEY-GENERAL: Not for the purpose in view. I am prepared to submit to your lordship that it would be immaterial.

Sir HORACE DAVEY: There are some details of the process, but all I wished to establish by M. Carré was that the carbon received the shape and form in which it appears in Swan's lamp before it was carbonised.

The ATTORNEY-GENERAL: As to that I must make some inquiry.

Mr. JUSTICE KAY: Do you admit that Swan got many of these carbons?

The ATTORNEY-GENERAL: No, I just admit the fact.

Mr. JUSTICE KAY: The only admission is that F I B 1 contains a carbon made by M. Carré, and that Swan got that from Carré.

The ATTORNEY-GENERAL: I further admit that the things in the green case were purchased from Carré.

Sir HORACE DAVEY: I will prove that.

Mr. JUSTICE KAY: What I have put on my notes is:—Admits that F I B 1 contains carbon made by Carré, and admits that Swan got that from Carré; will consider if he can admit that it was carbonised after it received its present shape.

Sir HORACE DAVEY: After the very fair way in which I have been met by the Attorney-General I will not press the application to have M. Carré examined in Paris.

The cross-examination of Prof. PERRY was then continued by the ATTORNEY-GENERAL.

Was not the first publication of electrical measurement in the *Telegraphic Journal and Electrical Review* of May, 1881, by Henry Madden, Alfred Meyer, and Prof. Thomas?—No, I do not think it was.

Will you produce an earlier one?—If I hunted for it I have no doubt I could.

Will you produce at any time an earlier publication of the electrical measurements of these lamps than May, 1880?—I am quite sure I could if I had time.

You shall have lots of time—days. You began in May, 1881, and on November 25th, 1881, there was published in the *Engineer* an account of the Paris Exhibition. Have you any earlier publications than those I have mentioned dealing with the same subject matter as the Paper of 1880?—It dealt with the subject of electric measurement.

Mr. JAMES SWINBURNE, examined by Sir HORACE DAVEY, said: I have had very great experience in the practical manufacture of lamps. I first saw Edison's lamp in the Paris Exhibition buildings, in December, 1881. I examined that lamp; it was the same as Dr. Frankland's exhibit—E F 1. As a practical lamp maker, I would say that was not made in accordance with the directions in Edison's specification. I have heard the evidence of Prof. Frankland and others on that point, and do not think there is anything to add. In my opinion that lamp certainly could not have been made from the directions in Edison's specification. I was first employed as a practical lamp maker at the Swan Works, at Gateshead, in the September of 1881. I stayed about a month or five weeks, then went to Paris to take charge of the works there, where I remained four or five months; after that I went to organise or start a very large incandescent lamp works in the United States, and since then I have been manager of the incandescent department of the Hammond Company. I am now scientific manager to Messrs. Crompton and Co. I am acquainted with all the processes in the making of incandescent lamps. When I was at Swan's I saw the process of carbonisation. They employed a particular mode of packing, which was secret then, but is not so now. The process was packing each filament in charcoal powder, with a little lampblack in it—a little division of a thing like a water-colour pallet. These pallets were then packed in the same powder in a large crucible or flagon, whose lid was carefully luted, and then carbonised by a very gradual raising to a high temperature. Several precautions are necessary in order to produce carbon for a practical lamp. There is the exclusion of the air. The carbons are liable to distortion. I was present when Mr. Gimingham gave his evidence. The frame produced by him and finally adopted I recognised having seen at the Swan Works. It was in use at the Swan Works, having taken about three months to work out. Mr. Alfred Swan, brother of Mr. Swan, did a large number of experiments. The difficulty was the distortion of the filaments during carbonisation. As you carbonise the wood slowly it gives off large volumes of protecting gases, and these prevent the consumption of the filaments. Swan tried a large number of experiments, some of which were under my eye. Filaments contract very much during carbonisation; if left loose they are very much distorted, and so you have to make a frame which contracts at the same rate and at the same time as the filaments themselves. The frame described by Mr. Gimingham was exactly the same as the frame we used. So far as I know, those appliances, in the way of surmounting the difficulties I have referred to, were certainly not known in November, 1879. Lane-Fox took out a patent to obviate those difficulties. Mr. Swan took out two patents for charcoal packing, and Edison I need hardly mention. Swan's is 5,014 of 1880. The necessity for precautions such as I have described is very great. A practical filament could not be made without using some of those precautions. I have tried to make a good filament of them. I made a number of such experiments in 1883, not for the purposes of this action or any other action. I made the experiments because I wanted, if possible, to bring out a lamp which had filaments made of some material not parchmentised. In 1883 I knew the advantage of having the thread parchmentised before being carbonised. The result of a large number of experiments was that I could not make a reasonably good filament. In 1883 I had been about two years engaged in work of that kind. I had acquired some experience in manipulating. I renewed those attempts in 1884 or 1885. The result was in these experiments I used every modern improvement I knew of, and I could not make commercial lamps of cotton thread not parchmentised. I used the most improved methods I knew of carbonising. At that time I was a lamp maker but wanted to simplify the manufacture. Putty or oxide of zinc I did not try. I never heard of anybody using them for practical purposes for making a useful lamp. I once tried packing the crucible with fireclay. That was in 1883; but the filaments were destroyed. I took every precaution known to me. I tried that experiment for the same reason as the parchmentising. Having been with Mr. Swan, I did not like to start on my own account with anything. This was Mr. Swan's invention. I did not wish the imputation of an old servant using his master's process. The reasons why this fine sand did not succeed were, first, that no luting is perfectly airtight, and oxygen gets into the cells; second, that there is a quantity of oxygen in the interstices of the powder which attacks the carbon of the filament; and, third, there is probably water in the fine sand. A filament may look perfectly right, and you do not find out its defects till it is put into a lamp. I have made experiments within a day or two as to carbonising in sand. I heated some red sand in a glass retort [retort produced] to low redness; air and water came off. I calculated that there was enough water given off to consume completely some hundreds of modern filaments. I made a second experiment with another kind of sand, which gave off enough to consume some

Digitized by Google

twenty-five to fifty modern filaments. The second sand was silver sand. I tried a third sand, grey coloured, and it gave off more water than the first. I weighed it, and found the volume of water vapour 27,000 centimetres. As to the practical result for the purpose of manufacture of filaments, I do not think packing with any kind of sand is a practical way. The copper spiral described in Edison's patent I do not think a practical way of making them. The copper would expand whilst the filament was contracting, and probably the filament would break for that reason. If the filament did expand so as to come out of the crucible whole, I think the workman would break it in manipulation. I made some experiments with regard to carbons mounted on platinum wires in 1881. I wanted, if possible, to avoid the necessity of making the large ends of the Swan filament. The result was the platinum was acted on by the carbon. The effect on the quality of the platinum was to make it very brittle, and I should think it was porous. I made a large number of other experiments in 1883 with a view to starting a Swinburne lamp. Some of the platinums were made like frosted silver, and others were quite black. I have examined the lamps which Mr. Gimingham produced. I agree substantially with everything Prof. Thompson said about those lamps. I have had some experience of flashing, and am acquainted with the process carried on at the Brush works. There are several necessary precautions observed—that the current does not increase unduly, that the filaments do not increase in diameter unduly, the less the better. In Cheesborough's process the precautions were not necessary. The purpose was to increase the diameter. As the carbon increased in size in Cheesborough's process the current would increase too. More current is required because there is a larger surface to heat. If you kept the current constant the temperature would fall as the carbon increased in size.

If I understand you rightly, as the carbon increases in size the current would itself increase?—It would of its own accord.

Examination continued: I have read Deprez's paper. Assuming the experiment on page 80 was an incandescent experiment, exactly the same thing would occur as Cheesborough mentions. Cheesborough does not add anything to Deprez. In flashing it is necessary to take precautions to prevent the current increasing, as it would if left to itself. I find no directions for that purpose in Cheesborough. Assuming the purpose of Cheesborough to be to cut sticks or pencils of carbon, the precautions I have just mentioned would not be necessary.

Would the directions in Cheesborough be sufficient to enable a workman to perform the process of flashing for the purpose you have told us?—Oh, no.

For the purpose of making carbons it would be sufficient?—Yes

I do not know whether you formed your judgment from reading Deprez's Paper as to whether he was using an incandescent experiment, on page 80?—I feel sure he was referring to an incandescent experiment.

Cross-examined by Mr. MOULTON: Do you say that in all cases, whatever be the source of your electricity, the temperature of the carbon will always increase during flashing?—Not if the resistance of the other part of the circuit is greater than that of the carbon; but that is an extreme case that I do not think Cheesborough could have contemplated.

Whether or not the temperature would fall if the carbon was left to itself would depend on the source of electricity, would it not?—It depends in a way on the source of the electricity.

In a case in which the carbon was of the same size and of low resistance, and the batteries of fairly high resistance, the temperature would fall very rapidly, would it not?—I find no mention in Cheesborough of batteries, but if Cheesborough used batteries and arranged them badly, what you say might take place.

Supposing Cheesborough was operating on a carbon of low resistance, and the batteries were of fairly high resistance, the temperature would fall very rapidly, would it not?—If you mean a whole set of batteries, it would.

In that case it would be necessary to take means to keep the temperature of the carbon up?—Certainly, it would.

You have been suggesting to his lordship that the resistance of the circuit of Deprez's batteries was high?—Certainly not.

What do you say it was?—Anything he chose. He could arrange in any way he liked.

Do you suggest if you were working a chain of batteries of ordinary pencil carbon the temperature would not fall rapidly?—Before answering the question you must tell me what you mean by a chain of batteries.

Supposing M. Deprez tried the experiment of passing electricity through carbon, as you suggest he did, in a hydro-carbon case with 100 cells arranged like that, do you suggest the temperature of the carbon would not rapidly fall as the flashing went on?—In the case of the carbon thread mentioned by him I think it would not.

In the case of either?—If he took a thick carbon and 100 single cells, arranged in series, I have no doubt the temperature would fall very quickly.

In Cheesborough's time those who used carbon in lamps used pencils of more or less considerable diameter?—I think so.

In the case of making a pencil of that diameter, or making a pencil from which other pencils could be cut, it would be necessary to take means to secure that the temperature would be kept up?—No, I think not.

I am putting to you the case of using batteries in which the interior resistance is considerably greater than the carbon?—If Deprez used batteries with the interior resistance of the whole battery greater than the resistance of the carbon he was treating, the temperature of the carbon would fall.

And so if they were equal?—If they were equal to start with they would fall.

Under these circumstances it would be necessary, would it not, to take means to keep up the temperature?—It would.

You state that Deprez was in this particular experiment on page 80 trying incandescence?—Yes.

Have you ever made a lamp like Cheesborough's?—Yes, to a certain extent like it.

Have you ever made a nitrogen lamp?—No, I have not.

Can you point to any paper which speaks of any such lamp being run at any such expenditure as 15 watts per candle-power lasting?—I cannot think of any one at the moment. I do not know whether there are any.

And you have made no experiments as to whether it is so?—No, I have not.

Do you suggest to his lordship that in 1879 it was not known that in order to conduct carbonisation carefully without destruction of the carbon, you must put carbon powder or something of that kind in the crucible?—From recent knowledge I cannot speak, as I was not in the trade then. I should think it was not known.

I am asking you whether it was common knowledge amongst chemists?—Oh, yes, amongst chemists it was common knowledge.

Do you mean to tell me anybody of ordinary chemical knowledge in 1879 would have any difficulty in understanding this question. "The whole is placed in a closed vessel free from air, and subjected to heat sufficiently to fully carbonise the fibre?"—I think they would.

Mr. JUSTICE KAY: They would have great difficulty in making the crucible free from air.

Examination resumed: Was it not well known that in the performance of such an operation carbon powder was the best way to keep it from the air?

Mr. JUSTICE KAY: No, it was not the best way of keeping it from the air; it was the best way of dealing with the air which was in it.

Examination continued: The two processes which you say were taken at Swan's factory in carbonisation were packing with charcoal powder and lampblack, and luting down carefully. In using these frames parchmentised the thread was wrapped up in long lengths?—It was.

So that the contraction of the thread in those long lengths would require some shrinkage of the wood that kept the carbon rods apart?—It would.

If the filaments were made singly—in other words, if cut before carbonised, there would be no need of that wood?—Do you mean putting the cut filament on the frame?

Cut filaments packed in charcoal in a crucible.—Cut filaments packed in charcoal in a crucible would get all sorts of queer shapes.

I would ask you whether or not the need for the wood was that you were making many filaments of continuous length?—In that particular case I should say it was.

Therefore, so far as the wood is concerned, if you were making filaments separately you would not want the wood at all? Would it not be useless?—Not necessarily.

If they were cut the wood would be of no good?—Not unless they were supported at the ends.

The Court adjourned at half-past one o'clock until the following day.

WEDNESDAY, MAY 9TH.

The ATTORNEY-GENERAL said: I desire to mention to your lordship that I have consulted my clients, and will now admit that the conductor F I B 1 received its present shape before carbonisation. I would ask my learned friend to admit—I think he has practically done so—that it came from France.

Sir HORACE DAVEY: It came from M. Carré.

The ATTORNEY-GENERAL: And Carré never was in England.

Sir HORACE DAVEY: I do not know that he never was in England. He carried on the business of manufacturing carbons, and sold them in France.

The ATTORNEY-GENERAL: I will also admit that, so far as we know, F I B 1 is made according to the description in *La Fontaine*, the translation of which was published in England in 1878.

The cross-examination of Mr. SWINBURNE was continued by Mr. MOULTON, as follows:—I refer you to articles published in *The Electrician* in the early part of last year. In the article published on February 18th, 1887, you began by saying, "Carbonising is simply raising the prepared manufacture to a high temperature out of contact with the air." That in your opinion was an accurate definition of carbonisation?—Of carbonising filaments, yes.

You go on to say, "The prepared threads or splints are placed in a closed vessel, and in a suitable furnace raised to a red or white heat?"—Yes.

You give a very long description of the exact working details of all this, and I take it that the process you describe is in your opinion a process of carbonising within the meaning of that definition?—Yes, I think so.

May I take it broadly that the methods are either to put carbon dust into the crucible itself, or to pack the crucible with carbon dust?—I think I described various other methods.

You have described an experiment of carbonising with kaolin. You say it did not succeed, first, because no luting is perfectly airtight?—I said that was one of the reasons why it did not succeed.

What kind of crucible was it?—It was either what is sometimes known as a carbon crucible or a little fireclay crucible. You might call it a fireclay crucible, I think.

Are such crucibles notoriously porous?—I do not think so.

Is it not a fact that danger arises from the oxygen which comes in through the cracks in the luting, not from that present in the crucible at first?—That is not quite the case. If your sand contains clayey matter there will be water coming off from it. Apart from the oxygen coming off the packing the destruction in long carbonisation is generally due to the oxygen getting in through the luting.

Therefore, if either outside or inside, the luting by packing charcoal dust will prevent destruction?—Yes; in a large measure.

Cross-examination resumed by Mr. MOULTON: In 1883 you applied

Digitized by Google

for a patent, and I will read to you the last sentence of the specification, as follows:—"For joining carbons to the terminal wires I propose to employ a cement wherein the carbonaceous matter is the basis, it being incorporated with a substance, which, on being heated, itself carbonises and cements the whole into a hard mass." Was not that a proposition on your part to use that very method for the purpose of uniting it to the terminal wires?—It is not the method of Edison. I have made lamps according to that.

I think lampblack would be called carbonaceous matter?—I tried lampblack, but it would not do.

"Incorporated with a substance, which on being heated carbonises," that would be tar?—What I was prospecting at the time was fuchnia or aniline dye.

Therefore you intended to take this cement and put it on the platinum wire. You did not mean to use clamps?—No.

You intended to use the platinum wire hot?—Yes, it was put through the glass before the cement was applied.

And then you intended to carbonise them?—Not in the sense in which you have used the word carbonise.

What is your operation in carbonising?—The ones I wanted to carbonise I held on the top of a piece of biscuit box with a gas flame underneath.

Heated them in the air?—Yes. I put something on which gave off some sort of gas; many of them were spoiled, some came out right.

I may take it that in 1883 you prepared a method of joining filaments on with the cement to the glass, which were carbonised upon a platinum wire?—I have made thousands of lamps in that way.

I asked you several questions on the subject of efficiency with regard to Cheesborough's process, and you told me Cheesborough's process did not increase the life of the lamp?—I told you flashing did not.

You were writing at the beginning of last year about modern filaments?—I was writing about every sort of filament I could think of.

You were only writing about filaments which were being commercially used?—Filaments that were being commercially used, or that I thought might be so.

Well, now, I will read you a passage from a Paper which you read February 25th, 1887, and is reported in *The Electrician*, p. 346. It is as follows:—"Flashing then tends to make a carbon that will run at the same surface temperature all over, which is not of necessity a carbon of uniform resistance. This is really what is wanted in a lamp, as durability of a carbon depends upon its temperature, or rather on the temperature of its hottest or weakest part." When you wrote that you meant to say that the flashing would greatly increase the durability of the lamp?—No; I meant that flashing would greatly increase the durability of the lamp if the filament is not uniform to begin with.

You told us that you were only writing about filaments that either were or might be commercially used?—I was.

Therefore I take it, at that date, February 25th, 1887, you thought that on such filaments flashing would have that effect?—With many of the filaments I have described here flashing would be very useful in increasing the durability of the lamp.

And according to your definition that would be increasing the efficiency of the lamp?—No. Efficiency of the lamp itself means nothing.

You would have to take into consideration the life of the lamp?—Yes.

But do you mean to say if it lengthens the life of a lamp according to your own definition it would increase its efficiency?—In the popular meaning of the word efficiency it would, but in the technical meaning it would not.

What do you say of the following:—"In a lamp it is required that the carbon should be all of the same temperature, and that that temperature should be the highest the carbon can safely stand, for the higher the temperature the higher the efficiency of the lamp?"—Yes.

Therefore, when you wrote that you meant it would, with many of those filaments, increase the efficiency?—No.

Comparing the efficiency of lamps in 1879 and 1887 there are improvements which greatly increase the efficiency in respect of the higher temperature which the carbons will stand?—For a long time, yes.

Has it not been shown that the use of this very method increases the actual brilliancy at the same amount of heat of a carbon by 30 per cent.?—I may explain that several lamp makers hold some opinion of that sort, but I believe no lamp makers who are aware of the great work done on the question of radiation would differ from me.

What works do you refer to?—Kirchhoff, for one.

Re-examined by Sir HORACE DAVEY: What do you mean by efficiency?—By efficiency I mean the ratio between the power absorbed and the light given out, or, in other words, the light-giving capacity of lamps at a given temperature.

You were not speaking of durability?—No.

Why do you say that flashing would not increase the durability of the lamp if the filament were uniform to begin with?—I say, from my own experience, a uniform filament is injured by flashing. I have made experiments with lamps having filaments, flashed and unflashed, and found a lamp with an unflashed filament more durable.

Mr. ALEXANDER BERNSTEIN, examined by Sir HORACE DAVEY, said: I am an electrical engineer, and have been engaged in electric light working for about 10 years. I have been a manufacturer of incandescent lamps for the last six years, and there is a lamp which bears my name and has been largely sold in the United States, Germany, and England. My lamps are essentially low-resistance lamps. The burner in my lamp is a straight rod of carbon. The rod is supported between two leading-wires, which leading-wires are sealed into the glass. The carbon rods made at the the present time vary in length between three-quarters of an inch and two and a-half inches, and the diameter is usually ·04 of an inch, or $\frac{1}{25}$th of an inch. I have sold as commercial lamps similar to that now shown me, A B 1. They have only lately been made, and I suppose about 1,000 are in use at the present time. There are installations of these lamps working in series, not only in England, but a far larger number in the United States, where there are about 80,000 now in use in circuit. That lamp has a carbon conductor attached to leading-wires, which are sealed to the glass, and the glass exhausted of air. I went to the United States in December, 1880. I was then interested in the subject of electric lighting, and had been for two years carrying on installations. I was exceedingly anxious to see the incandescent lamps in the market, and made repeated inquiries as to the Edison lamp, of which I had seen so much in the papers, but could not find any in the market or elsewhere. I first saw an Edison lamp in February, 1881, when Edison was giving an exhibition of his lamps at Menlo Park. People were invited. I went and saw the lamps. I examined the lamp, and made inquiries regarding it. [Shown E F 1.] Edison's lamp was a lamp of this kind. The leading-wires were attached to the filament in Edison's lamp by electro-plating. They were certainly not made by carbonising putty on the platinum leading-wires. The platinum leading-wires were continuous, as in this lamp. The filament was not made in the form of a spiral, but in the form of a loop, as this one is. I am quite certain the filaments were made out of carbonised bamboo fibre. The lamp was almost identical with E F 1; of that I am certain. In my experience I have never seen a lamp made simply from the directions in Edison's patent of 1879, and, from my knowledge, I think it would be impossible to make a lamp simply from the directions in Mr. Edison's specification.

Cross-examined by Mr. ASTON: When did you see any lamps like A B 1 which are now working in series in England?—In England the first lamp of this kind was in either August or September, 1886.

Where did you see them?—I am not in a position to give such information without injuring other people's business affairs.

I do not wish to press this witness, my lord, but I would like to know where these lamps were?—They are in use in works near Northwich.

Can you tell me whether there are any of these lamps within reach of this court?—There is one here.

I am serious; can you tell me whether there are any working in an installation within a reasonable distance of this court?—Certainly, there are quite a number at Commercial-road, Pimlico.

And they may be seen there?—Certainly, I will be happy to let you see them.

Is that your factory?—Yes.

I want to know whether they are in use in any other place than in your factory in London?—I do not think there is any installation at the present time in London. There was one, but the lamps are not in use now, as the lamps are not required.

Any other places?—It would be against the business interest of those connected with me to make any publication in which we put up our installations.

Mr. JUSTICE KAY: The witness tells you he has some objection to give further information on the point. I daresay he is afraid some persons interested may come against him.

Mr. ASTON said he would not press the point.

Mr. BERNARD PROCTOR, examined by Sir HORACE DAVEY, said: I am a chemist at Newcastle-on-Tyne. I have known Mr. J. W. Swan about 40 years. In 1878-79 Mr. Swan was carrying on business in Newcastle. I was not in any way professionally connected with him. At this time, besides his ordinary business, he was engaged in electric light, photographic light, and matters of that kind. He was engaged in the construction of incandescent lamps. I met Mr. Swan almost every day. I took an interest in the construction of incandescent lamps, and frequently assisted Mr. Swan in little matters connected with the lamps. Mr. Swan showed me every step in the progress he made about the time we speak of. I was secretary of the Newcastle Chemical Society, and President some years afterwards. I was present at a meeting on the 19th December, 1878. Mr. Swan exhibited a lamp which had broken down. He explained the construction of it to the meeting. He gave me the lamp, which I broke to get at the smoky deposit inside; I then sealed it together and now produce it. [Lamp produced.] That is the glass of the identical lamp produced by Mr. Swan, but does not contain the platinum or the carbon. That lamp has never been here before. The conductor was like F I B 1. The general construction was exactly the same. I remember being present at Mr. Swan's lecture at the Literary and Philanthropic Institute at Newcastle on 3rd February, 1879. He then exhibited a lamp and explained its construction. It was like F I B 1 now shown to me. My impression is that the lamp at the lecture had a thinner leading wire and a thinner carbon conductor. I produce wires which according to my recollection represent what was exhibited on that occasion. At that lecture the lamp was lighted with a dynamo machine. The lamp burned steadily from the time of lighting till it was put out by turning off the electricity. It could scarcely be called a good light compared with the lamps made now in 1888. There was an audience of 20 or 30 persons at the meeting of the Chemical Society in December, 1878. At the lecture in February, 1879, there was an audience of 600 to 800. On the 27th of March, 1879, I read a Paper on the smoke of an electric lamp before the Newcastle Chemical Society. The lamp I used then was this very broken lamp now produced. After the lecture in February, 1879, I continued to assist Mr. Swan in his researches. The examination of the smoke was made to assist him. I saw other lamps besides those used at the lectures, both before and after. I saw them in the various establishments of Mr. Swan. After the lecture of 3rd February, 1879, and before November, 1879, Mr. Swan made many improvements on his incandescent lamps. Within a day or two of the lecture Mr. Swan pointed out to me that the lamp could not be permanently a satisfactory one; he was aware that it took a large current. He also pointed out that the rigid connection of platinum, carbon, and glass were a source of weakness. I set to work to improve the lamp in these respects.

Digitized by Google

He endeavoured to remedy those defects by thinner carbons, and by making arched carbon, so as not to have leading wires at opposite ends of the lamp. During the period to which my attention has been directed I saw many other lamps besides those I have spoken of made by Mr. Swan, amounting probably to hundreds.

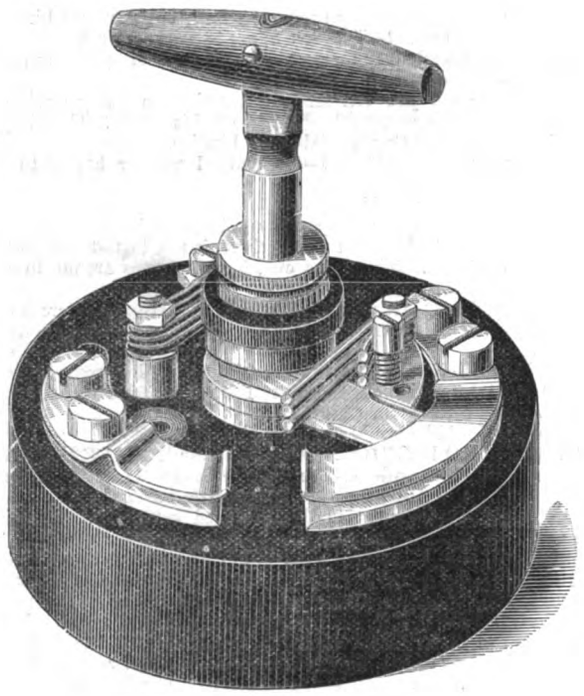
The ATTORNEY-GENERAL said he would submit that the seeing of those lamps by the witness at Mr. Swan's was not within the particulars of the case.

[Mr. BERNARD PROCTOR'S examination was continued at some length. Mr. A. W. HEAVISIDE was the next witness called, and the Court rose before his evidence was completed. On Thursday Mr. A. W. HEAVISIDE'S examination was concluded, and after some further evidence the Court again adjourned.

We are, however, unable to find room for the whole of the evidence down to the time of our going to press, preferring to stop short at Wednesday's proceedings rather than curtail the verbatim report, which we shall continue next week.]

SWITCHES FOR CONNECTING AND DISCONNECTING LAMPS AT VARIOUS POINTS IN THE CIRCUIT.

In our issue of the 20th January we described a simple method of arranging the wiring of incandescent lamps so that the same



lamp or group of lamps might be turned on or off from two different points. In the succeeding issue Mr. R. H. Neville pointed out that the device might be extended so that the same lamp or lamps might be turned on or off from as many different points as might be desired. A similar arrangement of 2-way switches has frequently been used in telephone work, in which the wits of the engineer are sometimes hard tested to provide subscribers with simple arrangements for all the combinations of circuit they require to be able to effect. For electric lighting purposes, however, we believe that the device was not in use before we drew attention to it.

The United Electrical Engineering Company inform us that they are now making switches of this design for a large retail establishment in London. They are to be used in the "furnishing" department. The attendant enters at one end of the gallery with a customer, and reverses the switch, thus lighting up; as he passes through the door at the other end he reverses the switch fitted there, and thus extinguishes the light. The switch is mounted upon a substantial slate base, and cannot be left in a neutral position; this, of course, is essential.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.—The directors recommend a dividend at the rate of £5. 7s. per cent. per annum for the year ending the 31st March, inclusive of the interim dividend paid in November last. A year ago the dividend was at the rate of 5 per cent., and there was a payment of 1s. per share by way of return of capital.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED) v. LA COMPAGNIE FRANCAISE DU TELÉGRAPHE DE PARIS À NEW YORK.

In our issue of the 13th January last we gave some particulars of this action, which was commenced in the Tribunal of Commerce of the Seine, and the judgment of that Court is given at length in our issue of the 27th January. The French Company appealed against the judgment to the Court of Appeal in Paris, and the appeal was heard on the 10th, 11th, 12th, and 27th April. The appellants were represented by M. Durier and M. Rodolphe Rousseau, and the Anglo-American Company by MM. Barboux and Nerot.

The arguments took place on the first three days, and on the 17th April the Advocate-General (M. Manuel), who appeared on behalf of the State, addressed the Court in a very able and comprehensive speech, which sets out all the facts of the case, and renders it unnecessary to report the speeches of the advocates on either side.

In the course of the discussion the appellants denied the competence of the Tribunal of Commerce to deal with the case, and repudiated the admission made by their counsel before that Tribunal that M. Cochery, the Minister of Posts and Telegraphs, in 1881 told M. Pouyer-Quertier, the President of the French Company, that his consent to the joint-purse agreement with the English Companies was unnecessary.

By the terms of the Concession held by the French Company all questions between the concessionnaire or the Company and the Government in relation to the Concession are to be decided "administratively by the Council of the Prefecture of the Department of the Seine, with appeal to the Council of State."

It will be seen from the report now given that the Court of Appeal has decided in favour of the Anglo-American Company upon the question of the competence of the Tribunal of Commerce, but has directed that the proceedings be stayed and final judgment postponed until the Administrative tribunals have decided the question whether the joint-purse agreement did or did not require the consent of the Government.

We understand that the case will be brought before the Administrative Tribunals as early as practicable.

The ADVOCATE-GENERAL expressed himself as follows:—Gentlemen, I think I may say without any exaggeration that the matter which has been submitted to the consideration of the Court presents itself under circumstances of fact rather exceptional, and which the Court will allow me to recall to it. It was in 1865 that the first transatlantic cable which was to connect Europe with North America was laid by an English Company, called the Anglo-American Telegraph Company—the respondent in the present action. Three years later, in 1868, the French Government granted Messrs. Erlanger and Reuter the exclusive right for twenty years of laying cables between France and the United States. Messrs. Erlanger and Reuter, in order to work this concession, had to, and in fact did, form with the aid of French capital a Company of the English kind. This Company necessarily entered into active competition with the Anglo-American Telegraph Company. This competition becoming disastrous to both Companies, they thought of amalgamating, and in 1873 the amalgamation between the two Companies was carried out with the consent of the French Government, which, however, made it a condition of giving its consent that it should resume its liberty of action, and that in future it should have the power of granting other cable concessions. The Anglo-American Telegraph Company consequently completely absorbed that which Messrs. Erlanger and Reuter had formed, and thus remained the only Company possessing transatlantic cables.

In 1875 another Company was formed in London for the working of a transatlantic cable—the Direct United States Cable Company. This new Company also entering into competition with the Anglo-American Telegraph Company, an agreement was brought about between them—a *modus vivendi*—which it has been agreed upon to call "the joint-purse arrangement." Making use of the liberty which it had recovered when it gave its consent to the amalgamation of the Anglo-American Telegraph Company with that formed by Mr. Erlanger, the French Government, represented by the Minister of Finance of the day, M. Léon Say, on the 7th January, 1879, granted to M. Pouyer-Quertier for himself and for the Company which he was about to form, the permission to land upon the French coast one or more cables for the purpose of connecting France with the United States. A schedule of conditions was annexed to this Concession, and in this schedule of conditions there is an Article 9 which plays an important part in the present contest, and which runs as follows:—

"The grantee, or the Company which may be formed by him, shall neither transfer any of the rights conferred by these presents, nor lease its lines, nor amalgamate its interests with those of any other Company, whether French or foreign, which is the concessionary of submarine transatlantic cables, without the express and written consent of the Government."

Beside this article, there are several others about which I must say a word. The first is Article 13, which runs as follows:—

"The authorisations conferred by these presents would become legally null and void, firstly, . . . secondly, . . . and thirdly, in the event of

Digitized by Google

failure to carry out the other essential clauses of the present Concession, and specially those formulated in Articles 9 and 11, as above."

As regards Article 14, it stipulated that in the event of the interpretation of the Concession giving rise to any differences between the Government and the concessionary, these differences should be submitted to the Council of Préfecture of the Department of the Seine, with the right of appeal to the Council of State.

The day after the Concession had been granted to M. Pouyer-Quertier—that is to say, on the 8th January, 1879—M. Pouyer-Quertier formed a joint-stock company under the title of "*Compagnie Francaise du Télégraphe de Paris à New York*," with an authorised capital of 42 million francs. It is this Company which is the appellant in the present suit. From that time there were three Companies in possession of transatlantic cables connecting Europe and America—the Anglo American, the Direct, and the French Company. There arose, as was bound to be the case, a war of rates between the two allied English Companies and the French Company. It is superfluous to say that this war of rates was injurious to all three Companies, but it was more particularly ruinous to the French Company. This war of rates was terminated by an arrangement, which was embodied in the Convention of the 24th September, 1880, which forms one of the main elements of the contest, and on which, therefore, I shall be obliged to dwell.

What, then, is the sum and substance of the Convention of the 24th September, 1880?

This Convention comprises several Articles. First of all, a word upon Article 1. This Article, which I will not read again, but only summarise, sets forth that the agreement—the subsequent Articles of which make known the scope—shall only become definitively binding after being ratified by the shareholders of the French Company assembled in general meeting, and provided that the Government authorisations which might be necessary shall have been obtained. Agreeably to the terms of Articles 2 and 3 of the same Convention, the receipts of each of the Companies for all the traffic traversing the Atlantic Ocean, after first deducting certain amounts due to the French and English Governments, shall be paid into a joint purse, and then the product of the joint purse shall ultimately be divided in the following proportions:—84 per cent. for the English Companies and 16 per cent. for the French Company. I shall shortly have occasion to give the explanation of these figures. The Court knows the working of this joint-purse arrangement. The product of the despatches forwarded to the other side of the ocean is always collected in France by the French Government. When a private individual hands in at a telegraph office a despatch, which despatch is to be forwarded to America, he pays the cost of the message, indicating the Company over whose line he wishes his telegram to be transmitted to its destination. Every three months an *employé* of the Government makes up a statement of the amounts received on account of each of the Cable Companies by the telegraph *employés*. After certain deductions have been made in favour of the French Government the balance is paid into the joint purse, where it swells the amounts paid in by the other Companies. At fixed periods the contents of the joint purse are ascertained, and distributed in the proportions mentioned. Thus much as regards the constitution of the joint purse. I must now say a word on Article 8 of the Convention. This Article is not without some importance in the case. It runs as follows:—

"The share capital of the Companies, and all properties, Concessions, authorisations, risks and perils respectively of the companies, shall remain entirely separate, independent, and distinct. . . . The results, good or bad, of their respective undertakings shall continue to belong each to their respective account. Lastly, it is expressly agreed and declared that there is neither amalgamation nor fusion of interests between them, but simply a *working arrangement* or agreement, leaving each Company its administration, direction, and particular *employés* and agents, who remain under the conditions of the present Convention entirely independent as regards the traffic, and free from all control or interference on the part of any one of the other Companies whatever."

Again, Article 10, which it is important to recall here, has for its object the fixing of the conditions of what has been called the Interruption Convention. It is an Article agreeably to the terms of which, when one of the Companies shall find its cable temporarily defective or broken, it may apply to another Company to forward its messages over that Company's cable. To this Convention of the 24th September, 1880, is annexed another Convention which the English documents term "Schedule," and which relates to the tariffs and regulations. Agreeably to the terms of the 1st Article, paragraph 1, of this schedule it is stated:—

"The charge for all telegrams between London and Paris and New York, forwarded over the lines of the three Companies, shall be such rate as shall from time to time be agreed upon between them."

Then, in paragraph 2 of this same Article, which in the printed copies has only two paragraphs, but which in reality in the original text must have had three, it is stated that until a new agreement is made the French Company shall receive 2s. per word as a minimum, and shall have the power of raising the tariff per word up to the maximum allowed by the Deed of Concession. The third paragraph of this Article 1 sets forth that the English Companies may at any time fix their tariffs as they like, but they shall not go below 2s. without the consent of the French Company. Then the same day the allied Companies entered into a subsequent Agreement, in which it was stipulated that the French Company should submit the Convention which had been entered into to the French Government, and should do its best to obtain its approval within a certain time.

On the 12th January, 1881, the shareholders of the French Company, assembled at an extraordinary general meeting, ratified by an imposing majority the Convention of the 24th September, 1880, together with the schedule annexed to it. On the 14th January this Convention was also ratified by the English Companies. A few days afterwards, on the 17th January, 1881, a further Convention was entered into between the French Company and the English Companies, the Convention which has been called "secret." I will shortly explain the relevancy of this word. What was this secret Convention? It is of great importance in the present contest.

The general meetings of the three Companies (it is stated in this Convention) duly ratified the original Convention. The French Company having submitted the said Convention to the French Government was assured that, agreeably to the true interpretation of its Concession dated the 7th January, 1879, this Convention did not require any approval of the French Government. The Convention of the 24th September, 1880, became definitely binding and was put into force.

On the 12th May, 1882, another Convention was entered into, that between the Anglo-American, the Direct and the French Company of the one part, and an American Company called the American Cable Company of the other part. The object of this Convention of the 12th May, 1882, was to admit the American Company to the benefits of the joint-purse arrangement, only the proportions in which the joint-purse was to be divided were altered. Agreeably to the Convention of the 24th September, 1880, the French Company took 16 per cent. of the total product of the joint-purse. By the terms of the Convention of the 12th May, 1882, it would not take more than 12½ per cent. The Convention of the 12th May, 1882, effected another modification in the Convention of the 24th September, 1880. The Court will remember the provisions of Article 1 of the annexed Schedule. Agreeably to the terms of paragraphs 2 and 3 of this Article the English Companies had a certain right relative to the fixing of their tariffs; but the paragraph states that the English Companies should never lower the tariff below 2s. per word, without the consent of the French Company. By the Convention of 12th May, 1882, paragraphs 2 and 3 of Article 1 of the schedule annexed are simply entirely suppressed.

For the present this is all I need remind you of respecting the Convention of 12th May, 1882. But this is not the only Convention entered into at that date. On the same day the four Companies which had just made the preceding Convention treat with four land line Companies, at the head of which is a Company called the Western Union. In this second Convention the contracting Companies undertook to hand over to each other the messages which had to be forwarded over each other's lines, and the American Companies undertook to establish at New York a central office as a terminus for all the telegrams. It was a sort of traffic arrangement, on which there is no occasion to dwell at any length, since it presents no difficulty as regards the present suit. It is desirable, however, to call the attention of the Court to a special point of this second Convention of the 12th May, 1882.

In addition to its cable connecting France with the United States, the French Company possessed on the American soil land lines extending from Cape Cod, the landing point of its cable, to New York. Now, the second Convention of the 12th May, 1882, contains, relative to these land lines, the following stipulation:—

"The land lines of the French Company between New York and Cape Cod, Taunton and Boston, and between Louisberg and North Sydney, shall be considered as a portion of the system of the parties of the second part (these were the American Companies) during the term of the present Agreement, but the French Company shall preserve not the less intact the full and entire ownership of the said lines, as stipulated in Article 12 of the present Agreement."

And in this Article 12 it is stated that the Western Union Company shall, at its own cost, maintain the lines in question in good working order. This is the only point to bear in mind in this second Convention of the 12th May, 1882. The land lines belonging to the French Company upon the American Continent shall be considered as forming part of the system of the American lines; but their ownership is nevertheless vested absolutely in the French Company. The maintenance and management, however, of these land lines shall devolve on a Company called the Western Union. This clause it seems has given rise to great disputes between the French Company and the Western Union—disputes which have been brought before the American tribunals, but with which the Court has no concern whatever in the present suit. All these Conventions were carried out up to the end of the year 1886, and as regards the principal one—that of the 24th September, 1880—it was carried out for nearly six years. But on the 30th December, 1886, the Minister of Posts and Telegraphs wrote a letter to the Managing Director of the French Company, which is worded as follows:—

"I have received the documents which I had asked you for by letter of the 23rd October last. Their examination shows that your Company, by amalgamating its interests with those of the Foreign Companies, is no longer under the conditions provided for by the cahier des charges (schedule of conditions) of the 7th January, 1879."

The very next day the Managing Director of the French Company acknowledged the receipt of this letter in the following terms:—

"Monsieur le Ministre. I acknowledge the receipt of your letter, &c., and I hasten to inform you that the Board of my Company, summoned as as of urgency, has just taken the necessary steps to put an end to the position the irregularity of which you point out."

We may do the Managing Director the justice to say that he acted with unprecedented rapidity, for the same day, December 31st, he not only assembled his Board, he not only replied to the Minister, but he also wrote to each of the Companies, parties to the Convention of the 12th May, 1882, communicating to them the Ministerial letter, and adding to it as follows:—"I have therefore the honour to inform you that, beginning from this day—December 31st—which closes the 1886 accounts, terminates the community of interests in which, according to the declaration of the Minister, we find that we have irregularly existed from the first of our Conventions up to the present time."

On the 17th January, 1887, the Minister acknowledged the receipt from the Managing Director of the French Company of the letter of the 31st December, saying:—

Digitized by Google

"By your letter of the 31st December you informed me that your Company's Board, summoned as of urgency, had just taken the necessary steps for putting an end to the position the irregularity of which I had pointed out to you. These steps can only be the denunciation of the agreements entered into between your Company and the foreign companies. I take note of your notification."

The allied Companies were not willing to admit that Conventions which had been in operation for six consecutive years should thus be suppressed by a stroke of the pen. This is why the Anglo-American Company summoned before the Tribunal of Commerce the French Company to have it declared that this Company should be made to resume the execution of these Conventions, under a penalty of 5,000 francs for each day's delay; and to have it condemned, in addition, to pay damages representing as many times 5,000 francs as there should be days elapsed between the 31st December, 1886, and that on which the execution of the Conventions should be resumed.

On the 9th January, 1888, was given the judgment appealed against. There is in this judgment a hiatus which is evidently attributable to an omission on the part of the copyist. The judgment mentions the Convention of the 12th May, 1882, only, and not that of the 24th September, 1880, which is the more important of the two. The grounds of the judgment are substantially the following:—If the Conventions entered into between the Companies, says the judgment, were only to take effect after obtaining the Government approval which might be necessary, it is acknowledged at the Bar of the Tribunal, and not denied:—1st, that the approval was asked for by the French Company; 2nd, that the Minister then in office declared his approval unnecessary because the Conventions did not fall within the scope of Article 9 of the Schedule of Conditions of the Concession granted to M. Pouyer-Quertier; 3rd, that upon the faith of this declaration the Conventions entered into between the parties were carried out during six consecutive years. The Ministerial letter of the 30th December, 1886, is therefore at variance with the preceding declaration. The mode in which it interprets the Conventions is new and unexpected. It cannot, under these circumstances of fact, constitute a case of "*force majeure*," for it is not even a command. Besides Article 14 of the Schedule of Conditions reserved to the French Company, in the event of any difficulties arising respecting the interpretation of its Schedule of Conditions, recourse to the Administrative jurisdiction. By failing to exercise this right, the French Company violated Conventions the maintenance of which was confided to its good faith, and gives ground for thinking that it was to its interest not to carry them out.

These, summed up in a few words, are the grounds of the judgment appealed against. As regards the decision itself, it is to the effect that the French Company shall resume the execution of the Conventions of 1880 and of 1882, until such time as the competent judicial authorities shall have definitively decreed as to the value of the Ministerial declaration of the 30th December, 1886, and this under a penalty of 5,000 francs damages for each day's delay. Then the judgment concludes with a condemnation to pay 2,000 francs for each day which may have elapsed from the 30th December, 1886, up to the day of the carrying out of the Conventions being resumed.

In the face of this judgment we have to examine two questions. First of all, we have to ask ourselves if the judgment has made a sound appreciation of the facts of the case? And afterwards, whether the judicial solution which it has given to them is acceptable to the Court? The first question which is raised by this dispute is this. Did the Convention of the 24th September, 1880, come within the provisions of Article 9 of the Schedule of Conditions, and was the Government approval necessary to make the Convention of the 24th September, 1880, possible, in order, and executory? No; say the English Companies. The approval was not necessary, because in Article 8 of the Convention of the 24th September, 1880, it had been expressly stated that there was no amalgamation—no fusion of interests—between the three contracting Companies. On behalf of the French Company it was replied to this that it was impossible to fail to acknowledge that on account of the creation of the joint purse there was at least a fusion of interests between the three Companies.

We are not required to give our opinion upon the first point. The solution of the difficulty can only appertain to the competent Minister. In 1881 three courses were open to the competent Minister—either to have authorised the execution of the Convention of the 24th September, 1880; or to have said that he refused to give his approval to the execution of this Convention; or to have said that there was no ground either for approval, or for its refusal, because the approval was not necessary seeing that the Convention of the 24th September, 1880, did not come within the prohibition of Article 9 of the Schedule of Conditions. It is certain that the competent Minister did not give any express and written approval. It is equally certain that he did not give any refusal of his approval. But the first judges say, that if the competent Minister neither granted nor refused his approval, it is because he deemed such approval was not necessary. The first judges add that certainly there was no document expressly stating this decision of the Minister; but that it was shown by matters of fact absolutely certain, and which were of a character to bring conviction to their minds. Is this estimate of the first judges correct? We believe so. It is based upon the acknowledgment at the bar by the two parties to the suit, that the Minister had declared that the Convention which was submitted to him did not come within the prohibitions of Article 9. That is what the tribunal expressly says, commenting upon what passed at its bar.

Observe that not the slightest attempt has been made to allege that the tribunal has misunderstood, and that it has given any other than their proper meaning to the words of the Agréé who had the honour of addressing it. Only before this Court the Appellant Company comes and says that if the tribunal made no mistake, the Agréé, to make amends, spoke with lamentable carelessness, that he made an incorrect statement which he had received no authority from his clients to make, and that if he had kept to his instructions he would have made an absolutely contrary statement. Is there ground for now admitting the disavowal thus thrust upon the Agréé? First of all, then, who conducted the defence of the French Company before the Tribunal of Commerce? It was Maitre Lignereux. The Court knows that he is one of the busiest and most experienced, as well as one of the most careful, Agréés of the Tribunal of Commerce. It seems to me utterly inadmissible that, making a speech in an affair of the importance this is, Maitre Lignereux should have lightly made this most material and most important statement, for the whole case lay in this statement. Admitting, which is impossible, however, that he did make this grave mistake, as his statement was most material, and would form the basis of the judgment, the final consideration having lasted a month, a letter of correction would have been received on this point, either from the French Company or from Maitre Lignereux himself, who would have had his mistake pointed out to him. Having stated this, Now can we doubt that the language of Maitre Lignereux was that which the first judges retained and recorded? How can we doubt it, in the face of the stubborn facts which we must now review?

On the 9th October, in execution of the Supplementary Convention, the French Company had at once applied to the competent Minister, the Minister of Posts and Telegraphs, for approval, foreseen by the Convention of the 24th September, 1880, and under date of the 22nd October, the Minister replied to M. Pouyer-Quertier:—

"By your letter of the 9th October instant, you submitted for my examination the agreement entered into between the Anglo-American Company, the Direct United States Cable Company, and the 'Compagnie Française du Télégraphe de Paris à New York' for the working of their cables. In order to complete the study which my department is making of the subject, I shall require to be in possession of various documents which are connected with this agreement., viz.":—[Here follows a list of the documents asked for].

The French Company immediately placed itself in communication with the Anglo American in London, which alone was able to forward some of the documents asked for by the Minister. It was in consequence of these communications that the general meeting of the shareholders of the French Company of the 12th January, 1881, was held, a meeting convened specially to consider the import of the Convention of the 24th September, 1880. And the Court will not have forgotten that at this meeting an important personage was present—we mean the delegate of the Minister. It is five days after this that we have the Convention of the 17th of January, 1881, in which it is stated that the French Company, having assured itself that, according to the correct interpretation of its Concession, dated the 7th January, 1879, this Convention did not require any approval of the French Government, it had been decided and agreed, &c., &c.

In the face of the facts which we have just brought out, has not this Convention of the 17th January, 1881, a special bearing and significance? It has been said that this Convention was a secret one. But for whom? For the public? Perhaps so; but there is no provision of the law requiring that this Convention should be made public. Secret as regards the parties interested? Yes, it has been said this Convention was kept secret from the shareholders of the French Company, by whom it should have been ratified. The answer to this is simple. There was not the slightest reason for getting the shareholders of the French Company to ratify a Convention entered into in order to show they were agreed that the Minister had declared that the Convention did not need to be approved. But is it really true that the Convention of the 17th January was a secret one as regards the shareholders of the French Company? The reverse is certain. For in the report which was submitted to them by the Board at the ordinary general meeting of the 11th May following we read as follows:—

"We will simply say to-day that we are glad that we proposed this Convention to you, and that the results are of a character not to make you regret having approved it. . . . Anxious at once to reap the benefit of it, we satisfied ourselves that the Government authorisations mentioned in Article 1 of the Convention were not necessary for us. From that time, nothing further preventing the Convention coming into operation, we agreed with the English Companies to put it into force forthwith."

It is therefore certain that it is somewhat to meet the requirements of the case that the Convention of the 17th January, 1881, has been termed a secret one. On the contrary, this Convention was not secret to anyone; it was known to all whom it could concern. What is the sum and substance of what is said respecting this Convention? It is said that the language attributed to the Minister of Posts was not held by him, and that the Directors of the French Company then in office deceived the Directors of the English Companies when they came to them, saying: We have satisfied ouselves by application to the Minister that his approval was not necessary. Who, then, is it that says that? It is the French Company itself, represented, it is true, by other Directors, but still it is the French Company, which for six consecutive years reaped the benefit of the Convention.

Now, who are they who are thus alleged to have played upon the credulity of the English Directors? They are honourable men, most of them very well known. They had at their head M. Pouyer-Quertier, Senator, formerly Minister of Finance and Minister Plenipotentiary, and who, in virtue of his position, necessarily found easy access to the Minister of Posts and Telegraphs. And these are the men who it is alleged banded themselves together to deceive the good faith of the English Directors! It is very difficult to believe this. Granting, however, for the moment that M. Pouyer-Quertier lied—for it was he who on behalf of the Board signed the Convention of the 17th January, 1881. Granting that he condescended to what has been characterised at the Bar as a trick of legerdemain. What *rôle* would they make then the Minister play? This high functionary

Digitized by Google

must then substantially have replied :—"I will not give you my approval —I will not refuse to give you the approval which you apply for either. Do what you like. Go! Make contracts, involve the most important interests. And if by chance I should happen to leave the Ministry, well, I shall be replaced by another Minister who will enjoy the same power as myself, and you will always be at the mercy of the caprice of the Administration!"

On such an assumption what opinion should we form of the good faith and justice of the Minister of the time, particularly when it is certain that he knew everything before the Convention was concluded, at the moment of the general meeting which ratified it, and subsequently to this ratification. The Court will remember that letter of the 24th August, 1882, which was read to it by the worthy Counsel of the Anglo-American Telegraph Company—a letter emanating from M. Pouyer-Quertier, and which was addressed to the Minister of Posts and Telegraphs. This letter related to questions of modifications of tariffs. The approval of the Minister was necessary in order to make these modifications. And M. Pouyer-Quertier, reminding the Minister of the interview which had taken place between them, says to him :—"I cannot agree to such and such of your demands because I must (first) have the assent of the parties who are interested with me."

Who were these parties interested with him? They were the Anglo-American, the Direct and the American Company—in a word, the parties to the Convention of the 12th May, 1882. And when M. Pouyer-Quertier thus spoke of the co-operation and approval necessary from the parties interested with him, it is obvious that the Minister of that time was perfectly aware of the Conventions of 1880 and 1882, particularly those of 1880, which had formed the object of special study on his part. Here there is a document which has a certain importance, and which has not been read to the Court. It is a letter dated the 2nd March, 1885, addressed by M. Riant, one of the Directors of the French Company who replaced the Chairman, to Mr. Weaver, Managing Director of the Anglo-American Telegraph Company, relative to the establishment, in the interests of both Companies, of a special wire from Brest to Havre. It is thus worded :—

"Dear Sir: By invitation given him by M. Cochery, M. Pouyer-Quertier this morning called at the Ministry of Posts, where he met your representative, who had also been summoned by the Minister. At this interview the following proposals were made. . . . Their object is to enable us to compete as advantageously as possible with the Commercial Cable Company."

And thereupon a long correspondence ensued, not only between the two Companies, but also between them and the Minister. In the face of all these facts, we declare that we entirely share the opinion of the Tribunal of Commerce.

The approval of the Minister was asked for in 1880, and at a date corresponding to that of the Convention of the 17th January, 1881, the Minister replied that his approval was not necessary. It is now that intervenes this Convention, which became the starting point of the execution of the Convention of the 24th September, 1880. But here an objection arises, which does not seem to have been submitted to the first judges, and to which the attention of the Court must be called; and all the more as in the note which has been circulated since the last sitting, on behalf of the French Company, this objection is taken up with much force. Let us examine it. The French Company says there is not only the Convention of the 24th September, 1880, there is also that of the 12th May, 1882. Now, if it may be considered that approval was asked for the Convention of the 24th September, 1880, and if it may be granted that the Minister replied that his approval was not necessary, it is certain that approval was not asked for the two subsequent Conventions of the 12th May, 1882, and that consequently the Minister could not have replied as to these that his approval was not necessary. Now, adds the French Company, the approval was all the more indispensable for these two Conventions of the 12th May, 1882, as they made the position of the French Company considerably worse than it was made by the Convention of the 24th September, 1880. In point of fact, it is said, the French Company, agreeably to the first of the two Conventions of the 12th May, 1882, took no more than 12½ per cent. of the product of the joint-purse. It lost its right of veto to the reduction of the tariff by the English Companies below 2s. per word. Then, agreeably to the Second Convention of the 12th May, 1882, the French Company leased its land lines on the American Continent to an American Company. Here was a veritable transfer of rights to which most certainly Article 9 of the schedule of conditions should be applied.

On behalf of the respondent Company it had been answered, and the answer is true in point of fact, that the Government approval was not explicitly stipulated in the first Convention of the 12th May, 1882, as it was in the Convention of the 24th September, 1880; that it was merely stated that the necessary authorisations should be obtained, and beyond the Government approval there were other authorisations to be obtained; that from the moment the Minister declared that his approval was not necessary for the Convention of the 24th September, 1880, it was not so either for that of the 12th May, 1882, because in fact it is a mistake to allege that this Convention, as well as that of the same day with the Western Union, changed for the worse the position which had been made for the French Company by the Convention of the 24th September, 1880.

The last estimate seems to us correct. And on this point the Court will allow me to enter into a few details which are not devoid of interest. First, agreeably to the terms of the Convention of the 24th September, 1880, the French Company took 16 per cent. of the product of the joint-purse. Under the Convention of the 12th May, 1882, it only took 12½ per cent. This question of proportion, when once the principle of the joint-purse is admitted, is of no importance. There is, however, one explanation which it is desirable to give the Court. When the Convention of the 24th September, 1880, was entered into, the contracting Companies possessed six cables amongst them, of which only one belonged to the French Company. One-sixth of the joint-purse was apportioned to it. When the Convention of the 12th May, 1882, with the American Company was entered into, the four contracting companies possessed eight cables amongst them. The French Company still had but one, and an eighth was allotted to it. It is unnecessary to dwell any longer on this first point.

Now, as to the allegation that by the Convention of the 12th May, 1882, the French Company lost the right of opposing the reduction of the tariff below 2s. per word, it is perfectly true that by the suppression of the two last paragraphs of Article 1 of the schedule annexed to the Convention of the 24th September, 1880, it is no longer stated that the English Companies shall not have the power of reducing the tariff below 2s. without the approval of the French Company. But it is not the less a fact that this reduction cannot take place without its consent. The Court will remember, indeed, the terms of Article 1 of the schedule. It is worded as follows :—

"The rate for all telegrams between London, Paris, and New York, forwarded over the lines of the three Companies, shall be such rate as may from time to time be agreed upon between the Companies."

This assumes the agreement of the contracting Companies.

Here, now, is Article 4 of the Convention of the 12th May, 1882 :—

"The tariff arrangements in pursuance of the present agreement shall remain the same as those borne on the schedule annexed to the agreement of the 24th September, 1880, which schedule, with the exception of the last two paragraphs of Article 1, and with the exception of the changes introduced into it by the present agreement, is hereby adopted by the contracting parties. But the rate for the transmission of cable messages between Europe and America, with the exception of those referred to in paragraph 2 of the said schedule, and of the service messages, shall, as soon as the necessary arrangements can be made, be raised to 2s. per word. It shall be maintained at this until it may be otherwise agreed by the contracting parties."

The tariff, therefore, cannot be lowered without the assent of the contracting parties. It has been argued, however, that the French Company might find itself in the minority, and that it would then be obliged to support the decisions of the majority. This, in our view, is a wrong interpretation both of Article 1 of the schedule, and of Article 4 of the Convention of the 12th May, 1882. It is obvious that, in order to modify the tariff rate, the four Companies must be in accord. It is thus that the French Company itself, as represented by the present Board, understands the matter. Here in fact is what was said to the shareholders at the general meeting held on the 25th May, 1887 :—

"Before making this concession (reducing the tariff to 60c.), had all the means of resistance conferred by the Conventions been exhausted?—We think not; and we persist in affirming that in virtue of Article 1 of this Convention, an absolute veto could be opposed to any reduction of tariff."

From this point of view, therefore, no alteration has been effected in the rights of the French Company by the Convention of the 12th May, 1882. But there remains a last point, the leasing of the land lines by the French Company. In the note which has been put in since the last sitting, this point is insisted on, and it is said the leasing of the land lines is unquestionably a transfer of rights, and so irrefutable is this proposition that even the opposite side has found nothing to reply to it. For our part we cannot admit the argument. The leasing of the land lines has nothing to do with the question. The French Company doubtless established them in virtue of a concession from the American Government. No doubt when the French Company came to take part in the second Convention of the 12th May, 1832, it was stipulated that these land lines should be in a certain measure abandoned by it from the point of view of actual possession. But it was stated at the same time that it would retain the ownership of them, and that only the management and maintenance of them would devolve on the Western Union Company. On what ground, then, should this special arrangement have been submitted for the approval of the Minister? Did it come under the application of Article 9? Was the Western Union Company the concessionary of submarine transatlantic cables? No; it was the concessionary of land lines. It follows as a consequence that the alleged leasing of land lines cannot be considered as coming under the prohibition of Article 9.

To sum up this part of the case, which has remained entirely outside the grounds of the judgment, it is true to say that if the Government approval was not necessary for the Convention of the 24th September, 1880, neither was it for the Conventions of the 12th May, 1882, since they did not alter the position of the French Company, as created by the preceding Conventions.

Let us now return to the consideration of the opinions of the first judges on the facts. After having established the fact that the Minister of Posts and Telegraphs of 1881 had deemed his approval unnecessary, they say that the interpretation arising out of the letter of the 30th December, 1886, was new and unexpected. New, it certainly was. No discussion is possible on this point. One might have even added "contradictory." Unexpected, there is no doubt about it, at least as regards the English Companies.

It must be admitted that the first judges characterised with some severity the conduct of the French Company in saying that it was wanting in good faith, and that it was permissible to assume that it was to that Company's interest that the Convention which it had voluntarily entered into with the English Companies should not be carried out. A few words only upon these two points. The Court is aware that in December, 1885, a new Transatlantic Cable Company was formed called "The Commercial." It is an American Company also known under the name of "The Mackay-Bennett Company." The Court knows that Mr. Mackay is a rich American, and that Mr. Bennett is the proprietor of a well-known American journal, the *New York Herald*. The Managing Director of the Commercial Com-

Digitized by Google

"By your letter of the 31st December you informed me that your Company's Board, summoned as of urgency, had just taken the necessary steps for putting an end to the position the irregularity of which I had pointed out to you. These steps can only be the denunciation of the agreements entered into between your Company and the foreign companies. I take note of your notification."

The allied Companies were not willing to admit that Conventions which had been in operation for six consecutive years should thus be suppressed by a stroke of the pen. This is why the Anglo-American Company summoned before the Tribunal of Commerce the French Company to have it declared that this Company should be made to resume the execution of these Conventions, under a penalty of 5,000 francs for each day's delay; and to have it condemned, in addition, to pay damages representing as many times 5,000 francs as there should be days elapsed between the 31st December, 1886, and that on which the execution of the Conventions should be resumed.

On the 9th January, 1888, was given the judgment appealed against. There is in this judgment a hiatus which is evidently attributable to an omission on the part of the copyist. The judgment mentions the Convention of the 12th May, 1882, only, and not that of the 24th September, 1880, which is the more important of the two. The grounds of the judgment are substantially the following:—If the Conventions entered into between the Companies, says the judgment, were only to take effect after obtaining the Government approval which might be necessary, it is acknowledged at the Bar of the Tribunal, and not denied:—1st, that the approval was asked for by the French Company; 2nd, that the Minister then in office declared his approval unnecessary because the Conventions did not fall within the scope of Article 9 of the Schedule of Conditions of the Concession granted to M. Pouyer-Quertier; 3rd, that upon the faith of this declaration the Conventions entered into between the parties were carried out during six consecutive years. The Ministerial letter of the 30th December, 1886, is therefore at variance with the preceding declaration. The mode in which it interprets the Conventions is new and unexpected. It cannot, under these circumstances of fact, constitute a case of "*force majeure*," for it is not even a command. Besides Article 14 of the Schedule of Conditions reserved to the French Company, in the event of any difficulties arising respecting the interpretation of its Schedule of Conditions, recourse to the Administrative jurisdiction. By failing to exercise this right, the French Company violated Conventions the maintenance of which was confided to its good faith, and gives ground for thinking that it was to its interest not to carry them out.

These, summed up in a few words, are the grounds of the judgment appealed against. As regards the decision itself, it is to the effect that the French Company shall resume the execution of the Conventions of 1880 and of 1882, until such time as the competent judicial authorities shall have definitively decreed as to the value of the Ministerial declaration of the 30th December, 1886, and this under a penalty of 5,000 francs damages for each day's delay. Then the judgment concludes with a condemnation to pay 2,000 francs for each day which may have elapsed from the 30th December, 1886, up to the day of the carrying out of the Conventions being resumed.

In the face of this judgment we have to examine two questions. First of all, we have to ask ourselves if the judgment has made a sound appreciation of the facts of the case? And afterwards, whether the judicial solution which it has given to them is acceptable to the Court? The first question which is raised by this dispute is this, Did the Convention of the 24th September, 1880, come within the provisions of Article 9 of the Schedule of Conditions, and was the Government approval necessary to make the Convention of the 24th September, 1880, possible, in order, and executory? No; say the English Companies. The approval was not necessary, because in Article 8 of the Convention of the 24th September, 1880, it had been expressly stated that there was no amalgamation—no fusion of interests—between the three contracting Companies. On behalf of the French Company it was replied to this that it was impossible to fail to acknowledge that on account of the creation of the joint purse there was at least a fusion of interests between the three Companies.

We are not required to give our opinion upon the first point. The solution of the difficulty can only appertain to the competent Minister. In 1881 three courses were open to the competent Minister—either to have authorised the execution of the Convention of the 24th September, 1880; or to have said that he refused to give his approval to the execution of this Convention; or to have said that there was no ground either for approval, or for its refusal, because the approval was not necessary seeing that the Convention of the 24th September, 1880, did not come within the prohibition of Article 9 of the Schedule of Conditions. It is certain that the competent Minister did not give any express and written approval. It is equally certain that he did not give any refusal of his approval. But the first judges say, that if the competent Minister neither granted nor refused his approval, it is because he deemed such approval was not necessary. The first judges add that certainly there was no document expressly stating this decision of the Minister; but that it was shown by matters of fact absolutely certain, and which were of a character to bring conviction to their minds. Is this estimate of the first judges correct? We believe so. It is based upon the acknowledgment at the bar by the two parties to the suit, that the Minister had declared that the Convention which was submitted to him did not come within the prohibitions of Article 9. That is what the tribunal expressly says, commenting upon what passed at its bar.

Observe that not the slightest attempt has been made to allege that the tribunal has misunderstood, and that it has given any other than their proper meaning to the words of the Agréé who had the honour of addressing it. Only before this Court the Appellant Company comes and says that if the tribunal made no mistake, the Agréé, to make amends, spoke with lamentable carelessness, that he made an incorrect statement which he had received no authority from his clients to make, and that if he had kept to his instructions he would have made an absolutely contrary statement. Is there ground for now admitting the disavowal thus thrust upon the Agréé? First of all, then, who conducted the defence of the French Company before the Tribunal of Commerce? It was Maitre Lignereux. The Court knows that he is one of the busiest and most experienced, as well as one of the most careful, Agréés of the Tribunal of Commerce. It seems to me utterly inadmissible that, making a speech in an affair of the importance this is, Maitre Lignereux should have lightly made this most material and most important statement, for the whole case lay in this statement. Admitting, which is impossible, however, that he did make this grave mistake, as his statement was most material, and would form the basis of the judgment, the final consideration having lasted a month, a letter of correction would have been received on this point, either from the French Company or from Maitre Lignereux himself, who would have had his mistake pointed out to him. Having stated this, Now can we doubt that the language of Maitre Lignereux was that which the first judges retained and recorded? How can we doubt it, in the face of the stubborn facts which we must now review?

On the 9th October, in execution of the Supplementary Convention, the French Company had at once applied to the competent Minister, the Minister of Posts and Telegraphs, for approval, foreseen by the Convention of the 24th September, 1880, and under date of the 22nd October, the Minister replied to M. Pouyer-Quertier:—

"By your letter of the 9th October instant, you submitted for my examination the agreement entered into between the Anglo-American Company, the Direct United States Cable Company, and the 'Compagnie Française du Télégraphe de Paris à New York' for the working of their cables. In order to complete the study which my department is making of the subject, I shall require to be in possession of various documents which are connected with this agreement., viz.":—[Here follows a list of the documents asked for].

The French Company immediately placed itself in communication with the Anglo American in London, which alone was able to forward some of the documents asked for by the Minister. It was in consequence of these communications that the general meeting of the shareholders of the French Company of the 12th January, 1881, was held, a meeting convened specially to consider the import of the Convention of the 24th September, 1880. And the Court will not have forgotten that at this meeting an important personage was present—we mean the delegate of the Minister. It is five days after this that we have the Convention of the 17th of January, 1881, in which it is stated that the French Company, having assured itself that, according to the correct interpretation of its Concession, dated the 7th January, 1879, this Convention did not require any approval of the French Government, it had been decided and agreed, &c., &c.

In the face of the facts which we have just brought out, has not this Convention of the 17th January, 1881, a special bearing and significance? It has been said that this Convention was a secret one. But for whom? For the public? Perhaps so; but there is no provision of the law requiring that this Convention should be made public. Secret as regards the parties interested? Yes, it has been said this Convention was kept secret from the shareholders of the French Company, by whom it should have been ratified. The answer to this is simple. There was not the slightest reason for getting the shareholders of the French Company to ratify a Convention entered into in order to show they were agreed that the Minister had declared that the Convention did not need to be approved. But is it really true that the Convention of the 17th January was a secret one as regards the shareholders of the French Company? The reverse is certain. For in the report which was submitted to them by the Board at the ordinary general meeting of the 11th May following we read as follows:—

"We will simply say to-day that we are glad that we proposed this Convention to you, and that the results are of a character not to make you regret having approved it. . . . Anxious at once to reap the benefit of it, we satisfied ourselves that the Government authorisations mentioned in Article 1 of the Convention were not necessary for us. From that time, nothing further preventing the Convention coming into operation, we agreed with the English Companies to put it into force forthwith."

It is therefore certain that it is somewhat to meet the requirements of the case that the Convention of the 17th January, 1881, has been termed a secret one. On the contrary, this Convention was not secret to anyone; it was known to all whom it could concern. What is the sum and substance of what is said respecting this Convention? It is said that the language attributed to the Minister of Posts was not held by him, and that the Directors of the French Company then in office deceived the Directors of the English Companies when they came to them, saying: We have satisfied ouselves by application to the Minister that his approval was not necessary. Who, then, is it that says that? It is the French Company itself, represented, it is true, by other Directors, but still it is the French Company, which for six consecutive years reaped the benefit of the Convention.

Now, who are they who are thus alleged to have played upon the credulity of the English Directors? They are honourable men, most of them very well known. They had at their head M. Pouyer-Quertier, Senator, formerly Minister of Finance and Minister Plenipotentiary, and who, in virtue of his position, necessarily found easy access to the Minister of Posts and Telegraphs. And these are the men who it is alleged banded themselves together to deceive the good faith of the English Directors! It is very difficult to believe this. Granting, however, for the moment that M. Pouyer-Quertier lied—for it was he who on behalf of the Board signed the Convention of the 17th January, 1881. Granting that he condescended to what has been characterised at the Bar as a trick of legerdemain. What *rôle* would they make then the Minister play? This high functionary

Digitized by Google

must then substantially have replied :—"I will not give you my approval —I will not refuse to give you the approval which you apply for either. Do what you like. Go! Make contracts, involve the most important interests. And if by chance I should happen to leave the Ministry, well, I shall be replaced by another Minister who will enjoy the same power as myself, and you will always be at the mercy of the caprice of the Administration!"

On such an assumption what opinion should we form of the good faith and justice of the Minister of the time, particularly when it is certain that he knew everything before the Convention was concluded, at the moment of the general meeting which ratified it, and subsequently to this ratification. The Court will remember that letter of the 24th August, 1882, which was read to it by the worthy Counsel of the Anglo-American Telegraph Company—a letter emanating from M. Pouyer-Quertier, and which was addressed to the Minister of Posts and Telegraphs. This letter related to questions of modifications of tariffs. The approval of the Minister was necessary in order to make these modifications. And M. Pouyer-Quertier, reminding the Minister of the interview which had taken place between them, says to him :—"I cannot agree to such and such of your demands because I must (first) have the assent of the parties who are interested with me."

Who were these parties interested with him? They were the Anglo-American, the Direct and the American Company—in a word, the parties to the Convention of the 12th May, 1882. And when M. Pouyer-Quertier thus spoke of the co-operation and approval necessary from the parties interested with him, it is obvious that the Minister of that time was perfectly aware of the Conventions of 1880 and 1882, particularly those of 1880, which had formed the object of special study on his part. Here there is a document which has a certain importance, and which has not been read to the Court. It is a letter dated the 2nd March, 1885, addressed by M. Riant, one of the Directors of the French Company who replaced the Chairman, to Mr. Weaver, Managing Director of the Anglo-American Telegraph Company, relative to the establishment, in the interests of both Companies, of a special wire from Brest to Havre. It is thus worded :—

"Dear Sir: By invitation given him by M. Cochery, M. Pouyer-Quertier this morning called at the Ministry of Posts, where he met your representative, who had also been summoned by the Minister. At this interview the following proposals were made. . . . Their object is to enable us to compete as advantageously as possible with the Commercial Cable Company."

And thereupon a long correspondence ensued, not only between the two Companies, but also between them and the Minister. In the face of all these facts, we declare that we entirely share the opinion of the Tribunal of Commerce.

The approval of the Minister was asked for in 1880, and at a date corresponding to that of the Convention of the 17th January, 1881, the Minister replied that his approval was not necessary. It is now that intervenes this Convention, which became the starting point of the execution of the Convention of the 24th September, 1880. But here an objection arises, which does not seem to have been submitted to the first judges, and to which the attention of the Court must be called; and all the more as in the note which has been circulated since the last sitting, on behalf of the French Company, this objection is taken up with much force. Let us examine it. The French Company says there is not only the Convention of the 24th September, 1880, there is also that of the 12th May, 1882. Now, if it may be considered that approval was asked for the Convention of the 24th September, 1880, and if it may be granted that the Minister replied that his approval was not necessary, it is certain that approval was not asked for the two subsequent Conventions of the 12th May, 1882, and that consequently the Minister could not have replied as to these that his approval was not necessary. Now, adds the French Company, the approval was all the more indispensable for these two Conventions of the 12th May, 1882, as they made the position of the French Company considerably worse than it was made by the Convention of the 24th September, 1880. In point of fact, it is said, the French Company, agreeably to the first of the two Conventions of the 12th May, 1882, took no more than 12½ per cent. of the product of the joint-purse. It lost its right of veto to the reduction of the tariff by the English Companies below 2s. per word. Then, agreeably to the Second Convention of the 12th May, 1882, the French Company leased its land lines on the American Continent to an American Company. Here was a veritable transfer of rights to which most certainly Article 9 of the schedule of conditions should be applied.

On behalf of the respondent Company it had been answered, and the answer is true in point of fact, that the Government approval was not explicitly stipulated in the first Convention of the 12th May, 1882, as it was in the Convention of the 24th September, 1880; that it was merely stated that the necessary authorisations should be obtained, and beyond the Government approval there were other authorisations to be obtained; that from the moment the Minister declared that his approval was not necessary for the Convention of the 24th September, 1880, it was not so either for that of the 12th May, 1882, because in fact it is a mistake to allege that this Convention, as well as that of the same day with the Western Union, changed for the worse the position which had been made for the French Company by the Convention of the 24th September, 1880.

The last estimate seems to us correct. And on this point the Court will allow me to enter into a few details which are not devoid of interest. First, agreeably to the terms of the Convention of the 24th September, 1880, the French Company took 16 per cent. of the product of the joint-purse. Under the Convention of the 12th May, 1882, it only took 12½ per cent. This question of proportion, when once the principle of the joint-purse is admitted, is of no importance. There is, however, one explanation which it is desirable to give the Court. When the Convention of the 24th September, 1880, was entered into, the contracting Companies possessed six cables amongst them, of which only one belonged to the French Company. One-sixth of the joint-purse was apportioned to it. When the Convention of the 12th May, 1882, with the American Company was entered into, the four contracting companies possessed eight cables amongst them. The French Company still had but one, and an eighth was allotted to it. It is unnecessary to dwell any longer on this first point.

Now, as to the allegation that by the Convention of the 12th May, 1882, the French Company lost the right of opposing the reduction of the tariff below 2s. per word, it is perfectly true that by the suppression of the two last paragraphs of Article 1 of the schedule annexed to the Convention of the 24th September, 1880, it is no longer stated that the English Companies shall not have the power of reducing the tariff below 2s. without the approval of the French Company. But it is not the less a fact that this reduction cannot take place without its consent. The Court will remember, indeed, the terms of Article 1 of the schedule. It is worded as follows :—

"The rate for all telegrams between London, Paris, and New York, forwarded over the lines of the three Companies, shall be such rate as may from time to time be agreed upon between the Companies."

This assumes the agreement of the contracting Companies.

Here, now, is Article 4 of the Convention of the 12th May, 1882 :—

"The tariff arrangements in pursuance of the present agreement shall remain the same as those borne on the schedule annexed to the agreement of the 24th September, 1880, which schedule, with the exception of the last two paragraphs of Article 1, and with the exception of the changes introduced into it by the present agreement, is hereby adopted by the contracting parties. But the rate for the transmission of cable messages between Europe and America, with the exception of those referred to in paragraph 2 of the said schedule, and of the service messages, shall, as soon as the necessary arrangements can be made, be raised to 2s. per word. It shall be maintained at this until it may be otherwise agreed by the contracting parties."

The tariff, therefore, cannot be lowered without the assent of the contracting parties. It has been argued, however, that the French Company might find itself in the minority, and that it would then be obliged to support the decisions of the majority. This, in our view, is a wrong interpretation both of Article 1 of the schedule, and of Article 4 of the Convention of the 12th May, 1882. It is obvious that, in order to modify the tariff rate, the four Companies must be in accord. It is thus that the French Company itself, as represented by the present Board, understands the matter. Here in fact is what was said to the shareholders at the general meeting held on the 25th May, 1887 :—

"Before making this concession (reducing the tariff to 60c.), had all the means of resistance conferred by the Conventions been exhausted?—We think not; and we persist in affirming that in virtue of Article 1 of this Convention, an absolute veto could be opposed to any reduction of tariff."

From this point of view, therefore, no alteration has been effected in the rights of the French Company by the Convention of the 12th May, 1882. But there remains a last point, the leasing of the land lines by the French Company. In the note which has been put in since the last sitting, this point is insisted on, and it is said the leasing of the land lines is unquestionably a transfer of rights, and so irrefutable is this proposition that even the opposite side has found nothing to reply to it. For our part we cannot admit the argument. The leasing of the land lines has nothing to do with the question. The French Company doubtless established them in virtue of a concession from the American Government. No doubt when the French Company came to take part in the second Convention of the 12th May, 1832, it was stipulated that these land lines should be in a certain measure abandoned by it from the point of view of actual possession. But it was stated at the same time that it would retain the ownership of them, and that only the management and maintenance of them would devolve on the Western Union Company. On what ground, then, should this special arrangement have been submitted for the approval of the Minister? Did it come under the application of Article 9? Was the Western Union Company the concessionary of submarine transatlantic cables? No; it was the concessionary of land lines. It follows as a consequence that the alleged leasing of land lines cannot be considered as coming under the prohibition of Article 9.

To sum up this part of the case, which has remained entirely outside the grounds of the judgment, it is true to say that if the Government approval was not necessary for the Convention of the 24th September, 1880, neither was it for the Conventions of the 12th May, 1882, since they did not alter the position of the French Company, as created by the preceding Conventions.

Let us now return to the consideration of the opinions of the first judges on the facts. After having established the fact that the Minister of Posts and Telegraphs of 1881 had deemed his approval unnecessary, they say that the interpretation arising out of the letter of the 30th December, 1886, was new and unexpected. New, it certainly was. No discussion is possible on this point. One might have even added "contradictory." Unexpected, there is no doubt about it, at least as regards the English Companies.

It must be admitted that the first judges characterised with some severity the conduct of the French Company in saying that it was wanting in good faith, and that it was permissible to assume that it was to that Company's interest that the Convention which it had voluntarily entered into with the English Companies should not be carried out. A few words only upon these two points. The Court is aware that in December, 1885, a new Transatlantic Cable Company was formed called "The Commercial." It is an American Company also known under the name of "The Mackay-Bennett Company." The Court knows that Mr. Mackay is a rich American, and that Mr. Bennett is the proprietor of a well-known American journal, the *New York Herald*. The Managing Director of the Commercial Com-

Digitized by Google

pany was Count Dillon, the same who in 1881 was the Managing Director of the French Company, but who was dismissed from his office in consequence of disputes relative to the ratification of the Conventions of September, 1880. The Commercial Company, this new comer, made a severe competition with the allied Companies. The latter would have very willingly made alliance with it, but the requirements of the Commercial Company were excessive. For its adhesion to the joint-purse arrangement it demanded that it should be guaranteed gross receipts of five million francs (per annum). The French Company, like the English Companies, would not agree to such conditions. It was thought that there was no other way of fighting the Commercial Company than by lowering the tariff to such a point as to render it impossible for that Company to continue the struggle. A decision was then came to by the allied Companies, under date of the 16th April, 1886, reducing the rate of transmission to 60 centimes per word. In order to induce the French Company to consent to this reduction, the other Companies had been obliged to guarantee it its working expenses, to the extent of one million francs *per annum*. The amounts paid in carrying out this guarantee were to be refunded without interest by annual payments extending over five years, and then only if the tariff should have been raised again. It was in fact the "déversoir" agreement, a Convention which is often made between the Government and companies for the execution of railway works. It was not a loan, neither was it a gift, but this matters little. The French Company had agreed to the reduction of the tariff to 60 centimes per word.

At the general meeting of the shareholders of the French Company held on the 23rd June, 1886, the members of the Board, after having reported the position of the Company, and particularly the Convention for the reduction to 60 centimes per word, proposed to the shareholders to pay a dividend of 5 francs per share. The amount was considered very small by certain shareholders. There were complaints and recriminations. It has been said that amongst the shareholders there were some who had only just become such, those created only for the formation of a general meeting. We have not to ask ourselves the question, is this true or false? As a matter of fact, the shareholders by a majority of 567 votes against 442 refused to approve the accounts. The old Board, composed of very distinguished men, was obliged to resign. It was replaced by a new Board, one of the members of which, M. Belleville, accepted the position of Managing Director. His first act was to demand of the English Companies the raising of the tariff. They replied that doing this would be playing the game of the Commercial Company, and renouncing at a dead loss advantages which had been obtained at the cost of considerable sacrifices. It is in the course of this correspondence that the Minister of Posts and Telegraphs wrote to the Chairman of the French Company, under date of the 23rd October, 1886, the following important letter:—

"By your letter of the 3d October instant (says the Minister) you have kindly informed me of the reconstruction of the Board. . . . I have the honour to acknowledge the receipt of this communication. I have been unwilling during the course of the difficulties which your Company has just passed through, particularly as regards the reconstruction of its Board, to ask you for information as to the rumours which were then circulated as regards the position of your Company *vis-à-vis* the English Companies. But now, in the face of the persistence and multiplicity of the allegations which daily appear in the newspapers, and according to which, contrary to the formal provisions of Article 9 of the Schedule of Conditions, the French Company is said to have amalgamated its interests with those of the Anglo-American Telegraph Company, I find myself compelled to ask you what foundation there may be for such allegations. I beg you, therefore, to give me very definite information, and, in case of need, that you will forward me copies of the agreements which may have been entered into between your Company and the Foreign Companies."

The next day M. Belleville sent the Minister everything which the latter had asked him for—without one word of explanation, without one word of protest. He said to him purely and simply:—"Monsieur le Ministre, I have the honour to send you the documents which you ask me for." No doubt M. Belleville will inform the allied Companies of what is going on. Here, in fact, is the Minister notifying that the position of the French Company is irregular—that it is not in conformity with Article 9 of its Schedule of Conditions, and that he will be compelled to take steps to put an end to this state of things. The commonest good faith required that M. Belleville should say to the allied Companies:—"You know our position is getting precarious. It is seriously threatened. Here is a letter which I have received from the Minister of Posts, dated the 23rd October." Well, it is acknowledged that this letter was not in any way communicated to the allied Companies.

Two months elapse, and on the 30th December, 1886, there arrives a letter from the Minister, in which he says:—"The examination of the documents which you forwarded me has shown me that your Company was irregularly constituted. I beg you therefore to take the necessary steps, &c., &c." And the next day, without one word of protestation—without any demand for explanations, without even applying for an audience—M. Belleville writes to the Minister:—"I have done what you wished. I summoned the Board as of urgency. Everything is finished, for I have written to the companies concerned that for the future the agreements would no longer exist." On the 27th January, 1887, an agreement was entered into between the French Company and the Commercial, by which the latter Company, in case of interruption, placed its cables at the disposal of the French Company, in consideration of the payment of the rate charged to the public by it, the Commercial Company. Here is an Agreement very speedily concluded, for it is dated the 27th January, and the Minister's letter the 30th December previous.

But it has been said on behalf of the French Company that the making of this agreement was imperative, and that it was not made at all under conditions indicating any complaisance whatever on the part of the Commercial for the French Company, for whilst the French Company was obliged to pay 1f. 25c. per word to the Commercial for the transmission of messages, it only received from the public 60 centimes. If things had indeed happened in this manner the French Company's position would have been a profoundly disastrous one, but happily for it the Minister intervened to lower the tariff in its interests. Here is, in fact, an extract from a circular from the International Office of Telegraph Administrations at Berne, bearing date the 1st March, 1887, and in which the manager of that office thus expresses himself:—

"Confirming my telegraphic circular of the 10th February last, I remind you that agreeably to a notification of the French Minister of Posts telegrams bearing the indication *vià P. Q.* during the interruption of the French Company's cable will be transmitted without any increase of charge (that is to say, for 60 centimes per word by the Havre route, Commercial Cable Company)."

We see then that this agreement with the Commercial Company entered into just after the letter of the 31st December, 1886, did not and could not have the disastrous result for the French Company which we have just pointed out as the necessary result of the difference of the tariffs (60c. and 1fr. 25c. per word). These are the facts. Do they justify the opinions of the Tribunal? In our view we must answer in the affirmative. Now do they justify the final provisions of the judgment? No; at least this is our opinion. It has been pleaded before the Court, and it had been previously summed up, that the Tribunal of Commerce was incompetent. This is a mistake.

The Conventions in litigation are essentially commercial Conventions, entered into between commercial Companies. One of these Companies, for some reason or other, refuses to carry out these Conventions. The other contracting Companies allege that it is without reason that it acts thus. They invoke the principle that agreements are the law of the parties to them. A dispute arises. Before whom should this dispute be carried? Unquestionably before the jurisdiction of common law, and in this particular case before the commercial jurisdiction. It was therefore properly brought before the Tribunal of Commerce.

But what will be done if the Company which refused to carry out the Convention maintains that it is released from carrying it out by the fact of Administrative acts which cannot be properly estimated by the Tribunal? The Tribunal will have to ask itself whether the Acts are so clear and so precise that one ought from the present moment to assert their execution, and if the reply is in the affirmative, it will decide in favour of the French Company, because the Administrative acts in question constitute a case of "*force majeure*" for it. If, on the other hand, any difficulty arises relative to the validity, the import, and the interpretation of the Administrative acts which are invoked before it, the Court should suspend its decision. The Tribunal of Commerce has manifestly exceeded its power. It violated the grand principle of the separation of powers when it ordered the French Company, under a penalty of 5,000 francs per day, to resume the execution of the Conventions of 1880 and 1882, and condemned it to pay damages on account of the non-execution of the Conventions in the interval comprised between the 30th December and the day they shall be resumed.

If, then, we admit the opinions of the first judges as to facts, we regret, on the other hand, the juridical consequences which they have drawn from them. What should the Court do? It ought either entirely to revoke the sentence of the first judges, on the ground that the Administrative acts invoked by the French Company having nothing doubtful in their character, that Company should not be held responsible for having interrupted the execution of the Conventions in litigation, since it was a case "*force majeure*" for it. Or, on the other hand, it should suspend judgment and send back the parties to the suit to apply before the competent jurisdiction for the interpretation of the Administrative acts produced in the contest.

We hold that there is ground for the Court to pronounce suspension of judgment, and for these reasons:—We have said that the Minister of Posts was the sole judge upon the point of knowing as to whether the Convention of 1880 and that of 1832 came within the prohibition of Article 9 of the Schedule of Conditions. If, therefore, only the Ministerial letters of the 30th December, 1885, and 17th January, 1887, were in question, as they are clear and precise, there would be ground for the Court to make the application of them, and to declare the resistance of the French Company well founded. But these letters are in contradiction with a preceding Ministerial decision, a decision revealed by a series of acts and decisive facts confirmed by the execution of the Conventions in litigation during six consecutive years, with the knowledge and privity of the competent Minister, and without either opposition, protest, or even objection on his part.

But we now come to the main objection raised by the French Company. Yes, it says, if there were a written decision of the Minister of 1881, stating that his approval was unnecessary, then we might admit the contradiction invoked. But such a decision does not in fact exist. It cannot either be deduced from circumstances, facts and acts, however plain, precise and clear their character. The decision, therefore, must be held as non-existent. This, in a few words, is the question. The Court, be it well understood, would not have the power to base an administrative decision on facts and acts possessing even the precision and clearness of those with which we have intentionally so long occupied its attention. But would not the administrative jurisdiction have this power? This certainly is a delicate question, which we are not called upon to decide. It is precisely for this reason, therefore, that we demand suspension of judgment, so that this question may be decided by the proper authority.

Suspension of judgment—such, in our opinion, is the proper juridical solution which the present suit admits of. In confirming this solution by making a suspension order, the Court will give another proof that it knows how to respect the great principle of the separation of powers, whilst at the same time giving to interests worthy of respect the legitimate satisfaction which in the name of equity they have a right to demand.

Digitized by Google

On the 24th April the Court (M. Perivvier, the First President of the Court, presiding) pronounced interlocutory judgment as follows:—

"Deciding upon the Appeal lodged by the *Compagnie Française du Télégraphe de Paris à New York* against the judgment given by the *Tribunal de Commerce de la Seine* under date of the 9th January, 1888.

"Upon the plea of incompetence propounded by the Appellant Company;

"Whereas the proceedings brought before the *Tribunal de Commerce de la Seine* had for object to make the *Compagnie Française du Télégraphe de Paris à New York* to carry out, under penalty of damages to be hereafter settled, the agreements entered into between that Company and the Anglo-American Telegraph Company (Limited) under the dates of the 24th September, 1880, and 12th May, 1882:

"Whereas these agreements both relate to the working of telegraph lines, of which the two parties to the suit are owners:

"Whereas these agreements belong directly to the domain of the Commercial operations which form the sole object of the said Companies:

"Whereas the questions to which they have given rise are agreeably to the terms of Article 631 of the 'Code de Commerce' within the competence of the Consular Tribunals.

"On the main question—

"Whereas in order to withdraw itself from the execution of the said agreements claimed of it and to justify the denunciation which it made of them under date of the 31st December, 1886, to the Anglo-American Telegraph Company, the appellant Company pleads a case of *force majeure*, which, according to it, would result from the injunction notified to it by Ministerial letter dated the 30th December of the same year, to return as of urgency to the conditions provided for and specified by Articles 9 and 13 of the Schedule of Conditions of the Concession prohibiting any fusion of interest with foreign companies without the express sanction in writing of the French Government:

"Whereas, if one puts against the above-mentioned Ministerial letter the execution during six consecutive years, with the knowledge and privity of the French Government, of the agreements of the 24th September, 1880, and 12th May, 1882, a serious doubt arises as to the precise meaning, character, and import of the despatch of the 30th December, 1886, from the point of view of the interpretation of the above-stated articles of the Schedule of Conditions of the Concession granted in 1879 to the French Company, and of the application which the Administration of Posts and Telegraphs claimed and claims to make of them, to the said agreements of the 24th September, 1880, and the 12th May, 1882:

"Under these circumstances there is ground for granting a stay of proceedings before definitively deciding, until the competent administrative authority shall have proceeded to the interpretation of the instruments and documents above mentioned.

"On these grounds,

"Without dwelling upon or recognising the plea of incompetence propounded, which is rejected as ill-founded,

"The Court suspends deciding upon the substance of the case until the competent administrative authority shall, on the proceedings of the most active party, have determined the interpretation of the Ministerial letter of the 30th December, 1886, from the point of view of the application which it intended and intends making to the agreements of the 24th September, 1880, and 12th May, 1882, of Articles 9 and 13 of the Schedule of Conditions of the Concession granted to the Compagnie Française du Télégraphe de Paris à New York, and reserves the costs for the purpose of their being decided upon at the same time as the substance of the contention."

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 28th*, 1888.

In one of my recent letters I made reference to the readiness and rapidity with which gas companies in all parts of the country were adopting the electric light as an adjunct to their present plant, or were consolidating with electric light companies, finding greater profit to lie in consolidation than in competition. Another feature of the present rapid extension of electric lighting is its union in the South and West with enterprises other than gas. In some parts of the South electric lighting plants are being run in conjunction with ice factories, which, serving as they do for refrigerating purposes, give a new extension and meaning to the well-worn old phrase, "sweetness and light." Just at present, too, a favourite enterprise is the combination of electric light plant with waterworks, and in some places, as at Hutchinson, Kansas, a telephone system is added, furnishing, it will be admitted, a peculiar diversification of industries under one roof. At Hutchinson, I am informed, the local company operates the Holly system of waterworks, a Thomson-Houston arc light plant, an Edison plant of incandescent light, and a large telephone exchange, the whole being under one ownership and management. In the waterworks department the company has a capacity of 5,000,000 gallons per day, with ten miles of mains and 108 double fire hydrants in service. The Thomson-Houston plant comprises a 50-light dynamo, and the incandescent branch includes six Edison machines of 2,400 light capacity. The electric light service is growing, and a fourth Armington-Sims engine is to be added to give the necessary power. The Telephone Exchange, it is interesting to notice, is equipped on the Cushman system, which is practically the only one left in the field to-day to contend with the Bell Company. The exchange has a capacity for about 200 subscribers, and nearly all the lines are rented. The whole plant cost about £45,000, and is regarded by the company as a very satisfactory investment. It is not at all unlikely that before long the station will be supplying current for an electric street railway; in fact, it is hard to say just where the limit to its usefulness will be found. The idea thus put into practice of combining several plants may not commend itself to your readers, but it has many advantages in point of economy and concentration.

Another idea, however, which is more likely to meet with favour is that carried out last week at Meriden, Ct., where the Street Railway Company, which is about to substitute electricity for animal power, invited Mr. Leo Daft to give a lecture on electricity, under the auspices of the Local Scientific Association. So much interest was taken in the lecture that the town hall of that busy city was crowded on the occasion with an audience of about 1,500 of the best people of the place. In order to illustrate his experiments Mr. Daft had a dynamo installed in a building near by, and thus had command of all the current necessary, and was enabled to deliver what is described as one of the most thorough and enjoyable dissertations on the subject ever given in New England. Mr. Daft, whose system has been adopted by the street railway company, paid special attention to motors in his lecture, and had on the stage with him a printing press from a local newspaper office, which was shown in operation, to the delight of the large gathering. It is evident that such a lecture must be beneficial in a variety of ways, not only in advertising the new power but in teaching correct ideas as to its nature and use.

Speaking of electric railways reminds me that Baltimore was last week the scene of another experiment in the way of storage battery cars. The Viaduct Manufacturing Company of that city has long been making experiments with the Faure battery, and as far back as the year 1885 had a car running at its works on a one-eighth of a mile track. The result of these experiments encouraged the gentlemen interested to construct a new car, and during the past winter, it has been equipped with Sprague motors. According to the newspaper accounts for that city the runs made last week were very successful. Over 150 miles of the worst track that could be found in that hilly city have been travelled, the car carrying a crowd of passengers at each trip without a single hitch, and the promoters of the enterprise are greatly encouraged. These experiments, it will be seen, have extended from first to last over a period of about five years, and therefore no want of persistence can be complained of. But the conditions were very different in 1883 from what they are now, and from what they will be in 1893. Five years ago there were no motors to be had in this country that were fit for street car work, and the storage batteries themselves were altogether crude. Now, with the motor in an advanced stage of improvement, and with the storage battery daily becoming cheaper and more efficient, it looks as if the sanguine expectations which have buoyed many enthusiasts up through weary years are very near realisation. There can be no question of the fact that the electric car has done enough to be accepted as an accomplished fact, and is the best for city street service that could possibly be desired. The leading newspapers in all our largest cities are emphatic in their demands for electric power. The committee of the Real Estate Exchange, which has been holding sessions here on the subject of rapid transit, has just reported to the effect that all rapid transit roads hereafter built shall be required not to use steam, but to put in either cable or electricity. They also

Digitized by Google

recommend that all the existing surface roads should be allowed to change over at once from animal power to cable traction or electric motor. Another significant utterance on the subject is that of Colonel Flad, not long since President of the American Society of Civil Engineers, and now President of the Board of Public Improvements in St. Louis. Being asked to give his views on the subject of street railway enterprises in Chicago, he has expressed his firm belief that while the introduction of cable railroads was naturally hailed as a great step in advance over the old system, its application will very soon be confined to the operation of lines on which heavy grades occur, and that the electric motor, in combination with the storage battery, will be used almost exclusively for the propulsion of street cars in cities.

The work for the current year of the New York Subway Board has at last been mapped out, and as it will begin in another week, it may be worth while to note one or two of the particulars. No fewer than 5,000 men are to be put to work at once on several sections, including the unfinished work of the last year and the completion as far as possible of the intermediate sections between the down town and up town districts. The work authorised, exclusive of Edison ducts in subway trenches, is 626,235ft. This work will occupy some three or four months. The construction company which carries out the work also recommends a new field for occupancy, which will require 615,000ft. of single duct. If all this work is done during the present year, New York will have one of the largest electric subway systems in the world. This activity is commendable, but it will also be more promising of the desired results to see greater willingness on the part of the electric companies to occupy the accommodation so liberally provided.

The New York Electric Club has just had its annual meeting. Mr. Hy. C. Davis has been re-elected president. Mr. Thos. A. Edison has retired from the management, and among those who have been added is Mr. T. N. Vail. From the statement made by Mr. Davis it appears that the total receipts from all sources for the year have been about $24,000. Of the $25,000 of bonds authorised about $16,000 have been subscribed for. The club is still in debt, however, to the extent of about $8,000 for furniture, &c., and another call by bonds has been made to the extent of $9,000, the subscription to which, together with the hoped-for payment of about $3,000 of back dues, and the addition of 150 new members in the year, will place the club on solid financial ground and free from debt. The club has proved a valuable addition to the social features of New York, and if managed on the right basis promises to be increasingly useful as a means of promoting kindly intercourse among men who are otherwise antagonistic, or not likely to meet.

Attention has been called this week to a new and interesting form of meter, designed by Prof. Elihu Thomson, in which the heating property of the current is employed as a means of effecting motion in the registering train. The apparatus consists essentially of two bulbs, which are attached to each other by a tube of narrow bore, or so arranged as to resist the rapid flow of liquid through it. Two small resistances are sealed into the bulbs; these bulbs are partly filled with alcohol, which is boiled, and the whole is sealed when the alcohol vapour has completely filled the interior space. At the top of a central pillar is a knife-edge support carrying the frame to which the bulbs and tube are attached. The suspension is so arranged that the centre of gravity is above the point of support, thus putting the arrangement in unstable equilibrium, tipping either way according to the excess of weight on either side. Mercury cups receive the ends of wires leading to the small coils in the bulbs, and according to the number of lamps in circuit the coils will be fed and heated, thus warming the liquid. This will result in evaporating the alcohol, in depressing the level of the liquid in the bulb, and cause the flow from one bulb to the other. The flow of the liquid into the one bulb from the other tips the apparatus and throws the current through the coil in the other bulb, when the action is repeated. Thus oscillation is set up and the register is moved, and a definite amount of current is shown to have been consumed.

Attention is called by the New York *Electrical Review* this week to the manner in which Mr. Wood, the President of the Sandusky Gaslight Company, recommended the Ohio Gasmen's Association recently to take up incandescent as well as arc lighting. Mr. Wood has advocated this change of front before, and now repeats his recommendations and endorsements. He referred to the incandescent lamp as the ideal domestic burner for illumination purposes, whose adoption by the public could not be prevented by the gas companies; and, "if that be true," said he, "to my mind the wisest course to pursue is to admit what we know to be true, and decide at once to supply the demand, increase our revenue, push it into the suburbs of our cities, sell it as cheaply as possible, and do not let others come in and take away what rightly belongs to us." This is notable language, and worthy the prominence given to it. That Mr. Wood's foresight is appreciated is shown by the fact that he has been elected to the presidency of the association.

Many of your readers will no doubt be interested to learn that the D'Humy battery is to be introduced on this side of the water. It has been taken up by a number of capitalists at Albany, the capital of this State, and I am told that the announcements in regard to it in the local papers there have provoked quite a sensation, as well as wordy warfare, among the local electricians, many of whom characterise the battery in terms more forcible than polite. I do not think we shall see much done with primary batteries in the lighting field just yet, but I know of two other experiments being made, one in Brooklyn by a young Englishman named Mason, who has just organised a company, and the other by a well-known and careful worker in this department, who has progressed so far as to light up the house of one of our leading electric light presidents.

CORRESPONDENCE.

THE LATE SIR CHARLES BRIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was much surprised and grieved to read in *The Times* of the 5th inst. the announcement of the death of Sir Charles Bright, and much regret that my absence from home will prevent my adding my humble wreath to the many which are sure to surround the last resting place of one so respected by all who knew him. Instead thereof perhaps you will allow me to place upon record through your columns my great appreciation of the many good qualities he possessed.

I first became acquainted with Charles Bright in Manchester in 1851, and since that time it has often been my privilege to be associated with him in many works. In 1853 subterranean wires were being laid from London to Manchester for the Magnetic Telegraph Company, Charles Bright as their engineer having to certify the completion of the sections of the same; and many are the instances known to me personally that I could quote of his great kindness of heart and goodness to all those with whom he was brought into contact on those occasions. I could speak in the same strain of him during the manufacture of the first Atlantic cables of 1857 and 1858, also of the Persian Gulf cables of 1863 and 1864.

In 1868 a cable was laid from Malta direct to Alexandria, of which I had the charge on behalf of the company who manufactured it, while Sir Charles Bright represented the company for whom it was laid. The same system of testing and of working was adopted in this case as in the Atlantic cables of '66, and I have a vivid recollection of the delight of Sir Charles when our first message was sent and correctly received, at what in those days was considered the high speed of 21 words per minute.

On that occasion I was fortunate in securing him as a companion to Marseilles, Messina, Catania, Syracuse, Malta, Alexandria, and the Pyramids, and a more congenial one it would be difficult to find, his good spirits and generosity being unbounded.

I have every reason to believe that the friendship thus

Digitized by Google

formed was as enduring on his side as on mine, and that our frequent meetings on the Council of the "Telegraph-Engineers" only served to cement it.

Trusting that his family, with whom personally I am not acquainted, will not consider this small tribute of respect to the memory of one whom I sincerely mourn intrusive.—Yours, &c., WILLOUGHBY SMITH.

May 8th, 1888.

"MAGNETIC RELUCTANCE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There is a tendency at the present time amongst some writers to greatly extend the application of the word resistance in electro-magnetism so as to signify cause/effect. This seems a pity, because the term resistance has already become thoroughly specialised in electro-magnetism in strict relationship to frictional dissipation of energy. What the popular meaning of resistance may be is beside the point, ditto dimensions, &c.

I would suggest that what is now called magnetic resistance be called the magnetic reluctance; and per unit volumes the reluctancy.—Yours, &c., OLIVER HEAVISIDE.

May 6th, 1888.

THE PAPERS OF FLEEMING JENKIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Permit me to suggest that the word "touch," which puzzles my friend Mr. Willoughby Smith, may be a typographical error for "hitch," due to indistinct manuscript. The substitution will make sense of the original.—Yours, &c.,

Valentia, May 7, 1888. J. GRAVES.

THE TELEPHONE INFRINGEMENT ACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It having come to the knowledge of the Equitable Telephone Association that the agents of the United Telephone Company are circulating reports to the effect that the association have not the intention or the means of defending the action for infringement of patent that the United Telephone Company have thought fit to commence against them, the association ask the favour of your space to give these most unwarranted reports an unqualified contradiction. They also take the opportunity of stating that not only have they the fullest intention of contesting the action to the utmost, but have also every confidence that they will be successful in upholding the freedom of their telephone.—Yours, &c.,

A. A. C. SWINTON, Director.

(For the Equitable Telephone Association, Lim.)

London, E.C., May 4, 1888.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

THE DEATH OF MR. THOMAS RUSSELL CRAMPTON.

At the commencement of the proceedings at the meeting held on Thursday, the 26th ult., the PRESIDENT said he had to announce the death of Mr. Thomas Russell Crampton, who had been a member for many years of the Society, and for some years a member of their Council, and who was so eminent as an engineer and contractor for railways that he need hardly say much about him, but merely call attention to the fact that he was one of the earliest pioneers of submarine telegraphy; and it was to his exertions that they were indebted for the present type of submarine cables throughout the world. The president then called upon Sir Douglas Galton to move a vote of condolence to the widow and family of Mr. Crampton.

Sir DOUGLAS GALTON said he was a very old friend of Mr. Crampton, and he felt satisfaction at having been called upon to move the resolution:—

That the members of this Society have learned with deep regret the decease of their much esteemed member Mr. T. R. Crampton, who was intimately connected with the establishment and laying of the first successful submarine cable, and they desire to express their sincere sympathy with his widow and with the other members of his family at the loss they have sustained.

Mr. Crampton, by his energy, his great science, and his great skill, was the person to whom the first submarine cable between Dover and Calais was due. An earlier line had been laid, which consisted of merely a wire covered with insulating material that very soon was destroyed. Mr. Crampton then came forward, and both raised the money and devised the cable which was subsequently laid in 1851, and that cable was really the origin of all the submarine cables which had been since laid. He (Sir Douglas) said the origin, because this form had been copied in every cable which had been successfully laid and successfully maintained until this day. He concluded by moving the resolution.

Prof. FORBES, in seconding the vote of condolence, said he endorsed everything that had been said by Sir Douglas Galton, having been intimately acquainted with the late Mr. Crampton.

The vote of condolence was unanimously accorded. The remainder of the proceedings was reported in our last issue.

[ERRATUM.—In our last week's report of the discussion on Mr. Crompton's Paper, page 751, 53rd line from the top, by an unfortunate printer's error the name of Mr. BERNARD DRAKE was omitted at the commencement of the paragraph containing his speech.]

PHYSICAL SOCIETY.

At the meeting of this Society held on the 28th ult., Mr. C. V. BURTON, B.Sc., read a Paper on

"Electromotive Force by Contact."

The author endeavoured to show by mathematical reasoning that there is not, as usually supposed, a definite and considerable E.M.F. produced by contact of two dissimilar substances, but that there is only a small E.M.F. due to gas effects at the separating surface, and depending either on chemical action or on absorption of heat.

Prof. AYRTON observed that there was no doubt of the existence of a marked potential difference when measured inductively. No experiments in which the quantity of gas present had been diminished as far as possible gave any indication of a diminution in the E.M.F. The evidence as far as it went was therefore in favour of the existence of a real contact E.M.F. of considerable amount, that is to say comparable to a volt. He did not consider that any process of reasoning apart from experiments would enable us to infer what would be the case in a perfect vacuum.

Prof. SCHUSTER referred to Prof. Lodge's Paper on "The Seat of the E.M.F. in a Voltaic Cell," and thought he had treated the air sometimes as a conductor and sometimes as a non-conductor, just as was most convenient.

Prof. S. P. THOMPSON observed that much of the discussion of this point had really arisen from different definitions of potential being taken. He did not agree with Prof. Ayrton that the gas plays no part, and referred to the experiments made by Mr. Brown, of Belfast, according to which the contact E.M.F. between two conductors was found to depend on the gas in which they were immersed.

Prof. AYRTON did not consider that Brown's experiment showed that the gas had any influence. The gases he used caused a visible oxidisation in the metallic surfaces, and this alteration of surface was sufficient to account for the observed differences in the E.M.F.

Prof. PERRY thought that the difference of opinion on the question arose entirely from the adoption of different definitions of potential.

Prof. SCHUSTER combated this statement, and pointed out that the question was, what would actually happen if two different conductors could be brought into contact in a space entirely free from air or other gas? And this did not depend on whether we adopted Sir William Thomson's definition of the potential of a conductor as the amount of work which would have to be done on a unit of electricity to bring it from an infinite distance to a point in the air infinitely near to the conductor; or MAXWELL's definition, which amounted to defining it as the amount of work which would have to be done on a unit of electricity to bring it from an infinite distance to a point within the conductor. He stated that by making some plausible hypotheses he had arrived at the conclusion that the amount of work done in bringing the unit of electricity within the conductor would be double the amount done in bringing it to a point in the air infinitely near to the conductor.

Mr. BURTON stated that he had adopted Sir William Thomson's definition of potential. He pointed out that Brown had obtained a series of successive reversals in the direction of the E.M.F. of contact by increasing the conductors alternately in air and in sulphuretted hydrogen, and this he considered showed that the difference in the effect in the two gases was not due to oxidisation.

Mr. H. TOMLINSON then read a Paper on

Digitized by Google

"A Theory Concerning the Sudden Loss of Magnetic Properties of Iron and Nickel."

Experiments by himself and other observers have shown that the temperatures at which iron and nickel lose their magnetic properties depend on the specimens used and the magnetising forces employed; but the temperature at which they *begin to lose* these properties is definite, for nickel about 300° C., and iron about 680° C. The author's own experiments on "recalescence of iron" show two critical temperatures, and Pinchon has shown by calorimetric measurement that between 660 and 720° C. and between 1,000 and 1,050° C. heat becomes latent. All these facts seem to indicate a molecular re-arrangement about these temperatures.

In his proposed theory he assumes that the molecules of iron, say, contain magnetic atoms capable of motions of translation and of rotation. These tend to form closed magnetic circuits, but at ordinary temperature are unable to do so, on account of the close proximity of their centres. On raising the temperature their centres are further separated, till at about 680° C. their polar extremities rush together, forming complete circuits, and exhibiting no external magnetic properties. On cooling down, the centres approach until the gravitation attraction overcomes the magnetic attraction of their poles, when the magnetic properties reappear.

Prof. AYRTON pointed out that iron had been shown to regain its magnetic susceptibility to a certain extent at a bright white heat, and lost it again when the temperature was increased beyond this point. He thought it would be of interest to endeavour to determine whether it would regain it again at a still higher temperature.

"Note on the Graphic Treatment of the Lamont-Frolich Formula for Induced Magnetism."

BY PROF. S. P. THOMPSON, D.Sc.

The formula referred to is $N = \overline{N} \frac{Si}{Si+b}$, where $\overline{N}$ = total induction when saturated, N = induction due to Si ampere turns, and b = value of Si, which makes $N = \frac{1}{2}\overline{N}$. Simple geometrical constructions are given for plotting the curve when $\overline{N}$ and b are known, and for finding $\overline{N}$ and b when two pairs of values of N and Si have been determined.

The use of the formula is shown to be justified in practice, for, as pointed out to the author by Prof. Perry, the curves connecting permeability, u, and induction B, are straight lines from B = 7,000 to B = 16,000, between which dynamos are usually worked. A method of pre-determining $\overline{N}$ and b is given for magnetic circuits of known form and materials, thus removing the objection often urged against the above formula, viz., that it involves two constants which had to be determined after the magnet was made. Two other "Notes" by the same author were postponed till next meeting.

COMPANIES' MEETINGS & REPORTS.

The Brazilian Submarine Telegraph Company (Limited).

The twenty-ninth ordinary general meeting of the shareholders of the Brazilian Submarine Telegraph Company (Limited) was held at Winchester House, 50, Old Broad-street, on Wednesday last, under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting, and the minutes of the last meeting, which were confirmed and signed by the chairman as correct.

The report of the Directors was taken as read.

The CHAIRMAN said that that was the twenty-ninth half-yearly meeting of the Company, and on every occasion on which he had met them he had been able to give a satisfactory account of the state of the Company's affairs. He was happy to say that on the present occasion there was no exception to that rule. Their plant was in excellent condition, their revenue was increasing every week, their expenses were diminishing, and they were paying off the debenture debt which they had been obliged to contract in order to complete the payment for the duplication of the cables. The expenses of the past half-year had been £449 less than for the previous half-year, which showed that the Board were doing all in their power to save money for the benefit of the shareholders. The amount of the debentures paid off and drawn for redemption—which, of course, would also benefit the shareholders—was £51,000, leaving a balance of £99,000 on the first issue. He had said that their plant was in good order, but there was one qualification to that statement, a small fault having developed itself a few miles from Pernambuco close in shore, which did not, however, in any degree interfere with the working of that cable, and which could be removed without much difficulty. They had entered into arrangements by which they would now obtain a repairing ship, and the fault would be removed as soon as possible. A fault had for some time shown itself in one of their cables off Madeira, and in repairing that during the past half year they had rather a curious experience. It seemed that at Madeira the two cables were conducted up the face of a precipitous rock into the cable house at the top. There was a tremendous hurricane at Madeira last winter, which blew those cables about to such a degree that the covering was destroyed, the two cables becoming so mixed, that in testing they thought there was a fault in the new duplicate cable instead of the old; they, however, discovered where the fault was, and had no difficulty in setting the matter right. It was satisfactory to know that, after the repair of the old cable, which had been submerged 14 years, it tested as well as it did when first laid, and that the portions picked up in order to effect the repair were in perfect order.

He then moved the adoption of the report and accounts.

The VICE-CHAIRMAN (Sir James Anderson) seconded the motion.

Mr. CUFF suggested that it would be a convenience to the shareholders if the Directors printed in the accounts the figures of the corresponding half year.

The CHAIRMAN said that they would consider the suggestion, but at the first blush he saw certain objections to it, not in regard to the shareholders knowing everything which the Directors could tell them as to the Company, but with reference to the general public.

Dr. TREWHELLA proposed a vote of thanks to the Chairman and Directors, and said that it was very gratifying to have the noble Chairman's assurance that their property continued in excellent condition.

Mr. CUFF seconded the motion, which was carried unanimously.

The CHAIRMAN, in reply, said that on the part of his colleagues and himself he thanked them for the confidence they had shown in the Board, and they would endeavour to deserve it.

The proceedings then terminated.

West Coast of America Telegraph Company (Limited).

The eleventh ordinary general meeting of this Company was held on Wednesday, at Winchester House, 50, Old Broad-street, Mr. Alfred Marshall presiding.

The SECRETARY (Mr. Fred. L. Robinson) read the notice convening the meeting and the minutes of the previous meeting, which were signed by the Chairman as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen—It is always a pleasure for the Directors to meet the shareholders and to be able to present a favourable report. I can congratulate you to-day upon the fact that the West Coast of America Telegraph Company has done a more satisfactory and profitable business during 1887 than in any previous year of its existence. In moving the adoption of the report and accounts I have to draw your attention to a few figures contained therein. The most prominent item on the income side is the gross earnings of the Company for the year 1887, which amount to £57,060. 15s. 8d., as compared with £42,340. 18s. 6d. for the previous twelve months. This is a very satisfactory increase of business, and, as mentioned in the report, it is almost entirely due to the larger number of messages transmitted by the company. We have also been favoured by a rise in the exchange. We charge for messages according to the currency of the country, and we find the exchange frequently varies to a considerable extent. In 1886 we were losers by its going down; but this year we have benefited by its rising in our favour. Those shareholders who have followed the published statements of the Company may be astonished at seeing the sum represented as earned in our report considerably higher than the figures which appeared in the newspapers indicated. This requires some explanation on our part. Up to the autumn of last year we were in the habit of publishing our gross earnings, which included the amount earned by the repairing steamer, but since that time we have adopted the principle acted upon by other cable companies of publishing merely the traffic returns, so that as our steamer has during the last year earned £500 a month, we have apparently done less business, but we thought it fairer to publish what we earned by our messages, as it might happen that this extra income of £500 a month might disappear in future in case the Company had to employ the steamer. For the present year we have secured the same earnings as the year before, and we are not without hopes that in the future we may continue in the same satisfactory position. There is an increase in interest account, which is due to our having had a larger amount of reserve to invest, and I hope to see this item grow very much year by year. The expenses which we have incurred during the year vary very little from those of the previous twelve months. One item was nearly £1,000 larger, namely, salaries and wages. The reason for that is that we have done more work, and we have required more clerks. We have a number of old clerks in our employment who have done their duty faithfully to the Company, and their salaries had been to a certain extent increased. And here let me remark that they have well earned that increase, because it has been owing to their careful attention to their work that the Company has been able to maintain its high reputation. The working expenses of the steamer have been virtually the same as they were the year before, so also are the office charges in London. We have had to spend about £1,700 more in repairing our cables—not a very large amount when you come to consider that we have to deal with over 1,700 miles of cable, and that breakages will occasionally occur. The only thing we can do in such cases is to make the repairs as rapidly as possible. I am happy to say that although we have had several interruptions to our cables, we were fortunate in being able to keep them down to a very short time, and sometimes with the assistance of the land lines we have been able to work during part of the time there were interruptions. After deducting all the expenses and the amount which we have to pay on our debentures regularly on the 1st of January and the 1st of July, there remained a net profit of £23,114. 18s. 1d., or adding the amount brought forward from last year, namely, £776. 16s. 5d., the total sum to be dealt with was £23,891. 14s. 6d.; out of this sum you have received in dividend £15,000, and we now ask you to sanction our proposal to write off from the

Digitized by Google

repairing steamer £1,557. 15s. 3d., reducing her value in the books of the Company to £17,500. Then we ask you to sanction the addition of £7,000 to the reserve fund, making it £27,000. We lay great stress on the importance of increasing this fund as much as possible, because in case of accidents it would enable us to make large repairs without being put to great financial inconvenience thereby. We are firmly convinced, too, that if we are able to show a larger reserve fund than we can at present the value of the Company's shares will proportionately rise in value. Our auditor, you will see by his certificate approving of the accounts, refers to the investment of £10,905. 12s. 6d. as having been realised. I quite agree with him that the investing of our reserve fund in debentures of our own Company is not quite desirable, however good a return it might yield, for in times of emergency the sum would hardly be available at a minute's notice, and we might not find people willing to take them at our price. Since the close of 1887 we have sold debentures at a profit, and invested them in securities which at any moment are convertible into cash, and which at the same time give us a fair remuneration. The remark of the auditor regarding our not making an allowance to the steamer for depreciation is answered by the amount that we propose to write off on this occasion. He concluded by formally moving the adoption of the report and accounts.

Mr. THOS. FIELDEN CAMPBELL seconded the resolution.

Mr. WELLS wished to know if there was any particular reason why the Company's accounts should be kept differently from those of any other company. By the way they were at present kept, and owing to the way the dividends were paid, the public were not able to fully appreciate the position of the Company. He thought it would be very desirable, too, if the auditors adopted the principle of other telegraph companies, and showed of what the investment account was composed. He thought it would be an advantage to have a detailed statement of it.

Mr. MASON could not agree with the last speaker as to the investment account. If their auditor was satisfied that the money was invested in a proper manner, and in accordance with the Articles of Association, he thought it would be more to the advantage of the Company that they should not know the particulars of the investments.

The CHAIRMAN: I can assure you that our auditor fully approves of the investments which we have made. As regards the payment of the dividends, we are only just now beginning, so to say, to get a firm hold of dividends. The previous year we were only able to divide 3 per cent, and I think we are approximating the policy of other companies by giving a portion of it in the middle of the year and a further distribution at the end of the year. Of course it lay in our power when we divided 3 per cent. at the beginning of the year, to give only 2 per cent. to our shareholders; but we thought it would please them better to receive the full amount that we thought we were justified in giving.

A SHAREHOLDER: Are the debentures terminable?

The CHAIRMAN: In 1902, when I hope we shall make an exchange at a lower interest.

The resolution was then put to the meeting, and carried unanimously.

On the motion of Mr. MASON, seconded by Mr. THORNTON, the retiring Directors, Mr. Alfred Marshall and Mr. Henry Roberts, were unanimously re-elected, as was also the auditor, Mr. J. Weise, on the motion of Mr. THORNTON, seconded by Mr. MASON.

The CHAIRMAN having briefly acknowledged this renewed mark of confidence, the proceedings terminated.

Submarine Cables Trust.

The seventeenth ordinary annual meeting of the certificate holders in this Trust was held on Tuesday, at Winchester House, Old Broad-street, under the presidency of Sir James Anderson.

The SECRETARY (Mr. Lewis Wells) read the notice convening the meeting and the minutes of the sixteenth annual meeting, which were confirmed by the present meeting, and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN: I have very few remarks to make, but some of them will give a clearer exposition of the report. Our revenue for the financial year which has just terminated was £17,948, as against £14 528, but in 1887 we brought into the accounts the large balance of £2,140, whereas we began this year with a balance in hand of only £95. In both years we have paid our coupons at the rate of 4½ per cent, but we carry forward to the current year a balance of £1,448, which, as stated in the report, is equal to an additional 8s. 6d. per cent. The interest payable on our certificates is cumulative, but our revenue has not enabled us to pay the coupons beyond those due on October 15, 1887, leaving the last coupon in arrear. The trust deed under which we work provides that interest shall be payable half yearly, viz., on 15th October and on 15th April. If we distributed the balance of 8s. 6d., which we have in hand, at once, the April coupon would have to be paid in three instalments, because in October next we shall not have sufficient funds to pay the whole outstanding £2. 11s. 6d. To avoid the inconvenience of paying one coupon by three instalments, your Trustees propose, with your approval, to hold the money in hand until October 15th, when they will pay £2 10s., and the balance of 10s. will be met on January 15th, 1889. On April 15th next year, we shall pay as much as possible on the October coupon. Due notice of the dates of payment will be sent to all the certificate holders who furnish the secretary with their names and addresses. In paragraph 3 of our report we refer to the falling off in our receipts. That is mainly owing to our investment in Anglo-American Company's stock, and I am sorry to say I do not know anything that I can at present add as to the prospect of that improving. The Eastern and Eastern Extension Companies—in which we hold a large amount of stock—are, however, paying very fair dividends—a fact which keeps up our revenue. By and bye, if the American "pool" companies can come to some agreement with their competitor, we hope to be in an improved position. For the present we are powerless in regard to that matter. With these few remarks I now propose

"That the report and accounts of the Trustees, now submitted to the meeting, be approved and adopted."

The Right Hon. VISCOUNT MONCK seconded the motion.

Mr. WEATHERBY made an inquiry as to the balance in hand on April 15, and was answered by the SECRETARY.

The CHAIRMAN put the motion, and it was carried unanimously.

The auditors, Mr. John G. Griffiths and Mr. John Gane, were afterwards re-elected.

Mr. WEATHERBY, in proposing a vote of thanks to the Directors, expressed a hope that they would do all they could to keep down the expenses as much as possible.

Mr. GRAY seconded the motion, and it was carried unanimously.

The CHAIRMAN: I am much obliged to you for the confidence you express in us. With reference to the expenses, we are always watching them in order to keep down the amount as far as possible.

The meeting then separated.

The Great Northern Telegraph Company.

This Company held its annual meeting at Copenhagen on Saturday evening, April 28th, when the Chairman, Mr. Tietgen, after reading the report, said that the state of the cables had been very satisfactory during the past year. In Europe there had been only four interruptions, which was an unusually small number, and in Eastern Asia there had been seven, which was also below the average. The repairs had been effected by the aid of the Company's cable steamers and engineers, with their usual skill and promptness. A question which has at all times been a most important one to telegraph companies, and one which always attracted general attention, was the life of a cable. Ignorant pessimists had put the limit at ten years because they had known instances of cables which had lasted no longer, but they had forgotten to mention the special causes for this short duration. These causes were, as a rule, external, such as an unfavourable condition of the bottom, &c., and less frequently owing to faulty manufacture of the cables. Others, including the Directors of the present Company, had taken a more hopeful view, although they expressed their opinions with the greatest caution, in the absence of reliable experience. Such experience had since been gained. Their oldest cable was the Danish-Norwegian, which had served close upon 22 years, but which in reality was older, as the Company's predecessors had bought it "second hand." It was of a somewhat primitive construction, and there was at the present time only about one-fourth of the original cable in use. The Anglo-Danish cable was put down in 1868, and had thus entered upon its twenty-first year. The state of this cable was altogether satisfactory, although it had been necessary to strengthen it at certain places, especially in the proximity of the English coast, where it was exposed to a considerable amount of trawling. Equally satisfactory is the state of the Scotch-Norwegian, the oldest Swedish-Russian, and the Danish cable, which are all 20 years old. Next in age came the Company's East Asian cables, which were now in fairly good condition. The principal mistake had been that their sheathing had been too weak to resist the dangers to which they were exposed. As a further illustration of this, he might mention that in the year 1870 a reserve portion of the same cable had been used in Europe—between Finland and Aaland—where the conditions of the bottom were very difficult, and of this cable, which was originally 57 miles long, there are only seven miles left of the original type—the rest had been renewed. All the Company's cables of a more recent date, both in Europe and Eastern Asia, are in an excellent state, including the French-Danish (dating from 1873), which for several years was the cause of considerable anxiety, until it had been strengthened in the right manner and in the right places. Their experience tended altogether to prove that the core of a cable resting perfectly undisturbed on the bottom of the sea is almost imperishable. This applies especially to gutta-percha cores, which the Company was adopting more and more. As to the sheathing, this could scarcely, even under the most favourable conditions, be said to be imperishable, though if proper materials were used a long life was possible. The shareholders had, he submitted, every reason to be satisfied with the state of the Company's cables. The principal events of the past year were the negotiations with the Chinese Government, which, the Chairman regretted to say, had not yet been brought to a satisfactory termination. About a year ago the Company, in union with its present ally in China, the Eastern Extension Company, commenced the negotiations with the Chinese Government. The representatives of the two companies, Mr. Henningsen and Mr. Judd, went up to Tientsin last April to lay their complaints and the proposals for a future arrangement before the Vice-King; the Managing Director of the Company at the same time visited St. Petersburg, where the Government desired minute information as to the Company's plans and intentions. The result was that the Russian Legation at Pekin was instructed to render the Company what assistance they could. The Vice-King referred the matter to the Chinese Director of Telegraphs, who resides at Chesoo, and the negotiations dragged on for the greater part of the summer. As was expected, the Chinese Government wanted to evade the concession of 1881, which was contended to be an illegal document, not having been sanctioned by the Tsung-li-Yamen, or what may be termed the Chinese Foreign Office. The Great Northern Telegraph Company had therefore framed an agreement between the two companies and China, which could take the place of the concession; but this draft did not, to begin with, meet with the approval of the Director for the Chinese Telegraphs. This official wanted a different base for the negotiations, and this had also been agreed to, although it would make the agreement more complicated. No sooner

Digitized by Google

had a fresh draft, however, been framed before the Chinese Government entirely abandoned their original views, and demanded fresh negotiations on the base of the Company's own proposal. Coupled with this were, however, several new demands, to which the Company objected and to which they only acquiesced after a considerable amount of pressure both from the Chinese Government and the Russian Legation at Pekin. The result was the Chesoo agreement of August 10th, 1887, signed by the representatives of the two companies and by the Chinese Director of Telegraphs on behalf of the Chinese Government. The Company had looked upon this agreement as a definite result, although not so favourable and satisfactory as wished for; but it had now rested with the Tsung-li-Yamen for seven or eight months for ratification without anything having transpired as to the fate of the agreement. Although the Chairman considered further discussion on the subject of this agreement, which might yet turn out to be stillborn, idle, he thought it expedient to correct some gross misrepresentations which had appeared in the Chinese press, and he also wanted to draw attention to the somewhat extraordinary proceedings of the Shanghai and Hong Kong Chambers of Commerce, inasmuch as these bodies had made objections against the agreement at head-quarters without knowing its contents. It had thus been circulated that the Company had paid China 100,000 taels for the agreement, and it had even been insinuated that this or other sums of money had found their way into the pockets of private Chinese individuals. No such thing had, of course, taken place; and, as a matter of fact, there would have been more occasion for the Chinese Government to try the power of gold with the Company than *vice versâ*, as the latter had only reluctantly accepted the agreement. The present state of affairs was this: that while the cables hitherto had transmitted the whole of China's telegrams to and from abroad, the time was now at hand when the Chinese land lines would obtain connection with the neighbouring countries' lines across the inland borders, and thus open new outlets for the traffic, against which the concession of 1881 would have protected the Company if it had been respected. What the Chinese telegraph authorities and the Great Northern Telegraph Company have now agreed upon is simply working hand-in-hand instead of against each other, by mutually influencing each other's rates and at the same time dividing the profits of the traffic, so that the profits for telegrams from and to those towns in China where the cables are landed mostly go to the cable companies, while the money for telegrams from and to other towns goes to the Chinese Administration. The public can of course choose what route they like. It had required a fair amount of resignation on the part of the Directors to accept this new order of things, as it will at once deprive the Company of a not unimportant profit derived from the traffic between Chinese towns, that are not "cable towns" and abroad, even if the public, which is probable for many years yet, will prefer the cables to the overland lines. And the agreement will further debar the Company from sharing in that increase of traffic which undoubtedly will take place to and from the interior of China when that country is opened for European progress. In lieu of all these sacrifices, the Company obtains the certainty of a *perhaps* less remunerative, but, on the other hand, more staple future in China. The Chinese telegraphs obtain, for their part, a considerable larger profit than they for some years could expect to earn if acting independently; but, on the other side, they give up an essential share in the profits on telegrams to and from the cable towns. That this agreement was a fair and just one, viewed from an impartial standpoint, would appear from the fact that both the English and the Russian Legations at Pekin had given the negotiations their support, as well as the whole of the Corps Diplomatique at Pekin. The *doyen* of the Corps Diplomatique, the German Ambassador, had announced the steps taken by the Hong Kong and Shanghai Chambers of Commerce as entirely unjustified and unfounded. Under the present circumstances it was impossible to predict what would be the final result of these long-pending negotiations, nor would the Chairman venture any prophecy as to what would happen. In order to be prepared for all eventualities the Directors proposed to put something substantial by for a rainy day. The Chinese Government had in the past year pushed their telegraph works with less energy than during the preceding years. The northern line he mentioned last year had been prolonged to the Russian frontier by two side lines, and the Yunnan line, *vid* Hankoo towards the south, had advanced to the border of Tonkin. These are the lines which have mostly brought about the negotiations referred to. China has further laid her first submarine cable in connecting the island of Formosa with the continent in the proximity of Foochoo. The Pescadores islands were at about the same time connected with Formosa. The Corean line has not yet been completed, a steamer, with cable on board, having been lost in the Red Sea. The Chairman had already last year stated that the Russian Government had introduced the Wheatstone system, by the aid of Danish telegraph clerks, between St. Petersburg and Irkutsk. A further step had now been taken in this direction by the engagement of a similar number of Danish gentlemen for the lines to the east of Irkutsk. The gross profits during the year 1887 amounted to 5,594,442kr. (including surplus from 1886), of which, fees for telegrams accounted for 4,806,717kr. The total expenses were 1,166,361kr.; of this amount 686,367kr. went to salaries, 164,682kr. to expenses connected with stations, agencies, &c., and 164,682kr. to the ordinary inspection of lines and cable steamers. The net profits were 4,428,080kr. of which 571,500kr. had been paid for interest and reduction of debentures. The shareholders had already obtained 5 per cent., or 1,350,000kr., and it was now proposed to give them an additional dividend of 4½kr. per share—equal to 675,000kr. To the reserve and renewal fund were added 1,000,000kr.; to the pension fund, 50,000kr.; to the Directors, 27,000kr.; and 754,580kr. were proposed being carried forward to this year's account.

The Directors' proposal was unanimously passed.

The CHAIRMAN also mentioned that it was the intention of the Company to make a good show at the forthcoming Copenhagen Exhibition.

West India and Panama Telegraph Company.

Report of the Directors for the half-year ended 31st December, 1887, to be submitted to the twenty-second ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Wednesday, the 16th inst, at twelve o'clock:—

1. The amount to credit of revenue is £44,945. 14s. 11d., and the expenses have been £24,884. 13s. 8d., leaving a balance of £20,061. 1s. 3d., which, with the balance of £1,826. 11s. 6d. brought from last account, makes a total of £21,887. 12s. 9d. Of this sum the Directors have placed £3,000 to reserve, leaving an available balance of £18,887. 12s. 9d., with which it is proposed to deal as follows:—

Payment of 10s. per share on account of arrears of dividend on the First Preference Shares	£17,281	10	0
Balance to current half-year's account.....	1,606	2	9
	£18,887	12	9

2. The traffic receipts for the six months show an increase of £3,623. 12s. 3d., as compared with the corresponding period. The gross revenue is also augmented by the profit on the charter of one of the repairing ships to a connecting Company, an improvement in exchange, and other exceptional causes.

3. The value of the cable used in the further repair of the original Jamaica-Porto Rico section, reported last November, amounts to £7,063, and has been, as on former operations on this section, charged to the reserve fund. The total expenditure for cable only, in restoring this important duplicate line is £31,331.

4. As must always be expected from the exceptionally unfavourable nature of the West Indian seas, numerous interruptions of cables have occurred during the half year, and the Company's two ships have been frequently engaged. Owing to the duplication of the greater part of the system the communications with the Colonies, except in one instance, have not been materially affected. All the cables are now in working order.

5. The Company's ss. "Grappler" is now on her way to London to take out 258 knots of new cable which is being manufactured under contract.

6. Should the International Conference on the question of the bounties granted by Continental States to their sugar industries arrive at a satisfactory conclusion, it is hoped that the result will be beneficial to West Indian interests.

7. In accordance with the Articles of Association, Charles William Earle, Esq., and William Ford, Esq., retire at this meeting, and offer themselves for re-election.

8. John George Griffiths, Esq., the auditor, also retires, and offers himself for re-election.

NEW COMPANIES REGISTERED.

UNITED KINGDOM TELEPHONE UNION (LIMITED).—This Company was registered on the 28th ult., with a capital of £10,000,000, in £5 shares, to carry on telephonic operations, with power to take over any existing business of a similar nature. The subscribers are :—

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended May 4th, 1888, amounted to £4,387.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of April, 1888, amounted to £1,800.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of April, 1888, amounted to £51,582, and to £43,136 in the corresponding period of 1887.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of April, 1888, amounted to £37,331, and to £35,965 in the corresponding period of 1887.

GREAT NORTHERN TELEGRAPH COMPANY.—The latest traffic returns of this company are as follows :—Receipts in April, 1888, £21,400 ; from January 1st to April 30th, 1888, £85,200 ; corresponding months, 1887 and 1886, £81,520 and £78,480 respectively.

ORIENTAL TELEPHONE COMPANY.—At the adjourned meeting of the shareholders of this company, to be held on Friday, the 25th inst., the proposed dividend of 2½ per cent., free of income-tax, for the past year, on the paid up capital of the company other than the vendors' shares, will be again recommended by the directors. The transfer books of the company will be closed from the 22nd to the 26th May, both days inclusive.

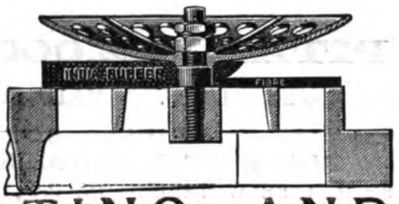
WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended May 4th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,649.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended April 30th, 1888, are £3,268, as compared with £3,027 in the corresponding period of 1887. The January receipts, estimated at £5,718, realised £5,965.

PERSONAL.—Mr. Basil Gee has taken charge of the London sales department for cable and wire of Walter T. Glover and Co., 10, Hatton-garden, E.C., and Salford.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

DRY DOCKS CORPORATION OF LONDON,

LIMITED.

This Corporation are owners of 20 Dry Docks, which include some of the largest in the Port of London, and have all the necessary appliances for executing the most extensive repairs to the Hulls and Machinery of Vessels. Estimates furnished on application to the Secretary, at the City Offices—

INGRAM HOUSE, 165, FENCHURCH STREET, E.C.

Offices—WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 522.—Vol. XXI. FRIDAY, MAY 18, 1888. Price 4d.

NOTES.

The Continuous *versus* Alternating Current discussion gives promise of perennial vitality. On Wednesday, at the Society of Arts, the redoubtable Mr. Crompton once more set forth the views with which our readers are now, perhaps, sufficiently familiar—this in addition to his reply last night at the Society of Telegraph-Engineers, which we shall report in due course in our next issue. A Paper on the same subject, which comes to us from Chicago (where it was recently read by Prof. F. B. Badt, before the electric club of that city), contains at least one point which we believe to be novel. Prof. Badt, like most electricians who are not partisans of a "system," believes that each method is good in itself, and has its own special field of usefulness. At the same time he is strongly impressed with the special economical advantages of transformer working, and his Paper is chiefly devoted to a consideration of the merits of that system for central station lighting. The point which we have referred to as novel is this, that in a high-tension alternating-current circuit, where the machine is separately excited, there is less danger to human life arising from an accidental break in the circuit than is the case with a continuous-current machine, where the field-magnets are in the same circuit. In the discussion which followed, Mr. Cutter, of the Thomson-Houston Company, stated that in their experience linesmen and others who had been accustomed to continuous currents, after working for a while with alternating currents, objected to go back to the former.

The beauty and ingenuity of the Van Rysselberghe system of simultaneous telegraphy and telephony has always been beyond dispute, but as a practical and efficient system we have from the first held that its application must be limited to circuits on which the telegraph service is not (as a rule) of a pressing character. It is largely for this reason that no use has been found for the system in this country, and the very considerable success which it has attained abroad is simply a proof of the comparatively low telegraphic development of the countries where it is found useful. This remark does not, of course, detract either from the merits of the invention or from its actual utility, nor should we deem it necessary to say this but for the extravagant claims which are continually being made by its supporters. In Switzerland, however, the weak points of the system are beginning to be admitted. It has recently been given up on the line from Geneva to Lausanne, and is now to be abandoned between Basle and Zurich. As estimates of the cost of the system are not easily attainable, we may mention that the equipments at these stations cost about £300 a piece. Dr. Rothen (Director of the Swiss Telegraphs), who has had considerable experience with the system, says that "although the ordinary Morse signals do not suffer, the Hughes printing apparatus is often deranged, and the employment of high-speed instruments, such as the Wheatstone, would probably be impossible." On this last point there can be little room for doubt. In addition to this, much larger batteries are required, and it has also been found extremely difficult to preserve the condensers from destruction by discharges of atmospheric electricity. From the telephonic point of view, Dr. Rothen says that the transmission is feeble, "and the extinction of the telegraphic signals is obtained only in theory." For all this the system has done, and will doubtless continue to do, good service where circumstances happen to lend themselves to its employment, and especially where the telegraph is second in importance to the telephone, and where the circuit is of copper wire.

The audience who assembled at Kensington on Friday evening last to hear Mr. de Tunzelmann's lecture upon the Telephone were privileged to witness some highly interesting experiments with Mr. C. A. Bell's "water-jet transmitter." Since it was shown last year to the Royal Society we believe that this is the first occasion of a public exhibition of this remarkable instrument. As a long-distance transmitter there is no doubt whatever that it is capable of yielding results of a far superior character to those obtainable from any carbon transmitter, simply because there is no limit to the amount of battery power which may be employed.

In the now classical Paper "On the Predetermination of Dynamo Characteristics" by Mr. Gisbert Kapp, every one will remember the striking and beautiful analogy pointed out by the author between an electro-magnet and a voltaic battery immersed in a conducting fluid. It was probably owing to the introduction of this concrete and readily understood illustration that the Paper owed much of its subsequent success in modifying and enlarging the views of dynamo builders; and the *kudos* due to Mr. Kapp for its discovery is in no way lessened by the circumstance which we are about to mention, namely, that it affords one more proof that there is nothing new under the sun. In the *Phil. Mag.* for June, 1852, there is a Paper by Faraday, in which occurs the following passage:—"The magnet . . . may be considered as analogous

Digitized by Google

in its condition to a voltaic battery immersed in water or any other electrolyte. . . . . I think the analogy with the voltaic battery so placed is closer than with any other case of *static* electric induction, because in the former instance the physical lines of electric force may be traced, both through the battery and its surrounding medium, for they form continuous curves, like those I have imagined within and without the magnet. . . . . No one, I think, will doubt that as long as the battery is in the fluid, and has its extremities in communication by the fluid, lines of electric force having a physical existence occur in every part of it, and in the fluid surrounding it. I conceive that when a magnet is in free space there is such a medium (magnetically speaking) around it. . . . . What that surrounding medium, deprived of of all material substance, may be, I cannot tell, perhaps the æther. I incline to consider this outer medium as *essential* to the magnet; that it is that which relates the external polarities to each other by carried lines of power; and that these must be so related as a matter of necessity." FARADAY proceeds to explain in what sense he uses the term *magnetic conduction*, which is of such frequent occurrence in the "Experimental Researches." In light of the last mentioned fact it seems hardly worth while to discuss the question to whom belongs the honour of inventing the term *magnetic resistance*. We understand, however, that a claim is put forward in this respect on behalf of EDISON.

AT the Physical Society on Saturday last some conversation took place with regard to Mr. OLIVER HEAVISIDE'S proposal (in the last number of *The Electrician*) to introduce the term "magnetic reluctance." A general disposition was shown to accept the proposal, both Lord RAYLEIGH and Prof. SILVANUS THOMPSON speaking in favour of its adoption.

MR. PREECE, on Thursday evening, remarked with great propriety that he wanted facts, and cared nothing for opinions. But when he went on to add "not even for the opinion of the editor of a technical journal," every right minded person will at once admit that for the moment Mr. PREECE went too far. But we are not at all angry—as the *Mikado* used to say; we know he did not really mean this, else why did he take so much pains to meet the criticism for which the technical journals were alone responsible? We shall, therefore, venture with confidence to ask Mr. PREECE'S careful perusal of our leader this week, wherein we have set forth at length our editorial views upon the subject under consideration.

UPON another point connected with technical journalism Mr. PREECE was good enough to offer *his* opinion, and we shall not be so rude as to say that we care nothing for it, because it happens to some extent to coincide with our own, and we are rather glad of an opportunity to say a few words on the subject. Mr. PREECE has the most decided objection to anonymous correspondence in the technical press. We may say at once that we believe our own record in this matter to be exceptionally good. A reference to the index which we published last week will show that out of 161 letters in our last volume only nineteen were signed with a *nom de plume*, and more than one-half of these were letters of inquiry from students and others. We have therefore no defence to make; nor, indeed, do we entirely agree with Mr. PREECE in this matter. While deprecating an unnecessary resort to anonymity, yet there are not a few cases in which the practice is perfectly justifiable. Such, for instance, as the case above mentioned of letters of inquiry. If a man wants to know the meaning of Ohm's law, and the editor cannot tell him, or for some reason does not wish to take the responsibility of doing so, does Mr. PREECE see any valid objection to his signing himself "An Ignoramus," or even for writing himself down as Dogberry desired? In other cases a signed letter might partake of the nature of an advertisement, for which due provision is made outside our correspondence columns. Or, to come to the point, in such a case as that under discussion, why should not the doings of a corporate body like the SOCIETY OF TELEGRAPH-ENGINEERS be subject to the unsigned criticism of those whose commercial interests are directly affected, if the writers find it desirable not to take sides too openly, and if the editor chooses to accept the responsibility of their insertion? On the other hand, we fully recognise and, as some of our correspondents have occasion to know, we act upon, the principle that anonymous letter-writing is an undesirable thing in itself, and not to be resorted to without good and sufficient reason.

UNLESS our esteemed contemporary the *Electrical Review* of New York has been made the victim of a very silly joke, the Mather Electric Company of Hartford, Connecticut, are responsible for the introduction of a startling innovation in dynamo-electric machinery. This is nothing less than placing the driving engine inside the armature! From the drawing accompanying the description, the engine appears to be of the Rigg type; it "is contained within a steam-tight metal casing, upon the outside of which the armature is mounted." The idea appears to us to be capable of still further development, for why should not the boilers be put inside the field magnets?

THE declaration of an interim dividend at the rate of 12½ per cent. per annum must be a very welcome announcement to the shareholders of "WOODHOUSE AND RAWSON (LIMITED)," especially as the sum carried forward is sufficient to have raised that dividend to no less than 40 per cent. But while heartily congratulating both the directors and the shareholders on the results attained, still, in view of the fact that further capital is to be called up and that the issue of 6 per cent. debentures to the extent of £30,000 is contemplated, it is desirable not to overlook the fact that the funds which have enabled the directors to produce these encouraging results have not been wholly derived from trading and manufacturing operations. A part of the profits—what part the Chairman did not disclose—is derived from financial transactions in connection with the UNIVERSAL AUTOMATIC MACHINE COMPANY. The directors are to be congratulated on the prudence and foresight which they have displayed in the matter—but, on the other hand, it is very evident that this is an entirely different thing from the

Digitized by Google

development of a permanent business capable of yielding such results as the above.

WE regret to notice the demise of our worthy little contemporary *The Telegraphist*, which, after a courageous struggle of about four years' duration, has had to bid farewell to the telegraphists. We are almost as sorry for them as we are for Mr. LYND, who vainly imagined that by supplying what would be useful to them in their profession he would earn their support. It would seem that they are a good deal more bent on getting their reward than on deserving it. Only the paper that will air all grievances, and invent them when none exist, finds favour with the spirits which at present rule the destinies of the British and Irish—especially Irish—operators. The singularly selfish views of their leaders have been lately revealed by the inspired questions with which the POSTMASTER-GENERAL is being continually pestered in Parliament—such, for example as how it comes to be that a clerk brought from the country is paid as much as one appointed in the capital?

Rome.—The General Post Office and the Central Telegraph Office in this city are now lit by electricity.

Interruption of the Barbadoes Cable.—We are informed that the cable between St. Vincent and Barbadoes is interrupted.

Theatre Lighting.—The Town Council of Olmütz has decided that the town theatre shall next season be lighted by electricity.

Buda-Pesth.—The business of Messrs. Bruckner, Ross and Co. (which was the oldest electrical firm in Austria) has been taken over by Messrs. Ganz and Co.

Southampton.—The Southampton Town Council has decided to seek the necessary powers to borrow £1,440 for the purposes of an experimental electric light installation.

Kojeteim.—The sugar factory of H. Redlich, in this town, is being fitted up with an extensive Edison installation, by H. R. Bartelmus. M. F. Jehl is the consulting engineer.

St. Etienne.—We learn with regret that the Edison underground main system has not proved satisfactory at St. Etienne. In many cases the subscribers are going back to the use of gas.

Kiel.—Bremen and Co., of Kiel, are employed at the present moment upon a central station for arc and incandescent lamps in the Imperial Torpedo Works at Friedrichsort, near Kiel.

Barcelona Exhibition.—The pavilion set apart for the Queen of Spain at the Barcelona Exhibition is being fitted with telegraphic and telephone apparatus for the exclusive use of Her Majesty.

Cable to the Azores.—Portuguese advices state that a contract was signed in London on April 26th between the concessionnaires of the submarine cable to the Azores and a leading English construction company.

Verona.—The local company which was recently formed here for the purpose of establishing a central station has been obliged to abandon the scheme. The gas company, however, is about to undertake the necessary works.

Buenos Ayres.—A correspondent writes to say that during a very heavy storm in Buenos Ayres, on the 2nd inst., a house was struck by lightning, causing the death of two young men, brothers, who were inmates at the time.

Electric Light Breakdown.—The Vienna correspondent of *The Times* states that on Wednesday evening, 16th May, the Austrian Jubilee Industrial Exhibition had to be closed "because the electric lighting went wrong."

The Edison Company in Egypt.—It is announced that the representative of the Edison Company has entered into negotiations with the Egyptian Government to light the principal towns, commencing with Cairo and Alexandria.

Vienna.—We understand that an extensive addition will shortly be made to the electric lighting plant in the new Town Hall in Vienna. At the present moment there are over 650 lamps installed, and this number it is proposed to raise to over 2,000.

Mr. Crompton on Electric Lighting from Central Stations.—At a meeting of the Society of Arts, which was held on Wednesday evening last, at which Colonel Hamilton presided, Mr. R. E. B. Crompton read a Paper on "Electric Lighting for Central Stations." The Paper was almost entirely of a non-technical character.

Variability of Magnets.—The *Centralblatt für Elektrotechnik* mentions a Deprez ammeter (Breguet pattern) which they recently had reason to re-calibrate. When new 26 amperes gave a deflection of 44 degrees; but on re-calibrating the same deflection was obtained with a current of 17·3 amperes.

Baudot's Printing Telegraph.—The Italian Telegraph Department have recently acquired the rights of Baudot's quadruple printing telegraph. The apparatus in question is already working satisfactorily between Rome and Paris, and in all probability it will very shortly be adopted on other important lines in Italy.

Thetford.—Electric lighting has recently been adopted at the St. Nicholas Iron Works, Thetford. The residence of Mr. C. Burrell, the owner of the works, is also lit by the current. Gas costs 5s. per 1,000ft. at Thetford, and our informant states that many tradesmen and others in this district are anxious to have a central electric lighting station.

Brussels Exhibition.—The Anglo-American Brush Electric Light Corporation (Limited) have entered into an important contract with the Executive Committee of the Brussels Exhibition for the lighting of part of the buildings and gardens by means of arc lamps, and will have the sole right to supply the light to stall exhibitors and others within the area covered by their contract.

Breslau.—The committee nominated by the Town Council of Breslau to report upon the best way of lighting the town by electricity, recommend the construction of a large central station to supply 5,000 lights, within a radius of 1,200 metres from the station. The committee propose that Messrs. Siemens and Halske, of Berlin, should erect the necessary works, and that the town should run the installation. No definite decision has yet been arrived at.

Toulouse.—The central station at Toulouse, which has been already at work for several months, will shortly receive a very considerable extension. The proprietor, M. de Chanteau, has obtained permission to make use of a fall of water at Bazacle, which it is anticipated will provide a force of 1,200 horse-power. The gas company at Toulouse has just completed the electric lighting of the theatre, a job which they have had twelve months in hand.

The Lighting of the Tunnels on the Kieff-Odessa Line.—This is a chapter of the Snakes in Iceland type. We stated some few months ago—on the authority of a Continental journal—that the tunnels on the railway line between Kieff and Odessa had been lit by electricity. We now learn from a source at

Digitized by Google

least equally authentic that there are no tunnels on the line between Kieff and Odessa. It therefore seems probable that they are *not* lit by electricity.

The International Society of Electricians.—The annual general meeting of this Society has just been held in Paris, when the following appointments were agreed to :—President : M. P. Lemonnier. Vice-Presidents : MM. Becquerel, Bergon, Carpentier, Gariel, Marié-Davy, and Lebert. Secretary : M. Seligmann-Lui. Secretaries of Sections : MM. D'Arsonval, Hospitalier, De Vasonty, Napoli, Sartiaux, and Vivarez. Treasurer : M. Dumoulin-Froment.

Students' Conversazione at the Technical College, Finsbury.—The annual students' *conversazione* of the Finsbury Technical College will be held on Friday, May 25th, commencing at 7 p.m., when a lecture will be delivered by Prof. S. P. Thompson on "Polarisation of Light," and a lecture will also be delivered by Prof. J. Perry on "Magnifying Springs." A concert will be given during the evening. Tickets may be obtained from the office of the college.

Mexico.—Advices from the city of Mexico report that new poles for the electric light are being daily erected in different parts of the city. The extension of the electric light appears, however, to have had a curious effect in producing an abundance of sand-flies and cockroaches in the city. According to a local scientist they both hail from Lake Texcoco, attracted at night by the electric light. Many varieties of insects, even if not nocturnal in their habits, are said to be thus attracted.

Middlesborough.—An entertainment was given a few days since at Borough-road, Middlesborough, by the district manager of the Northern District Telephone Company. The company had two transmitters at the Tyne Theatre, Newcastle, where the Carl Rosa Opera Company were performing, connected to a direct line running to the Middlesborough Telephone Exchange, thence to Borough-road, where nine receivers were placed round a table and connected. The company assembled heard the opera from beginning to end; not only were the words clearly rendered, but the least variation in expression was distinctly audible.

The Paris Exhibition of 1889.—All our readers, and particularly those who remember the valuable services rendered by Mr. John Aylmer, of Paris, as Secretary to the English Commission of the Paris Electrical Exhibition of 1881, will be glad to learn that the committee presided over by the Lord Mayor for carrying out the British Section of the Paris Universal Exhibition of 1889 have appointed him their hon. secretary in Paris. We are sure that a better selection could hardly have been made, and that Mr. Aylmer's management will render the larger Exhibition next year, as far as the English section goes, as great a success as that of 1881.

Telephones in France.—Inter-urban telephonic communication in France is now in many cases no longer limited to the offices at either end. At Paris, Havre, Lille, and Brussels, the subscribers can henceforth talk to one another from their own homes. The subscribers wishing for this additional privilege pay an extra sum of 50fr. per annum. This does not dispense with the charge for each five minutes' conversation, which is 1fr. between Paris, Lille, Rouen, Havre, and Rheims, and 3fr. between Paris and Brussels. The number of subscribers is as follows :—Between Paris and Havre, 85; between Paris and Lille, 145 ; between Paris and Brussels, 12.

The Late Sir Charles Tilston Bright. — At the weekly meeting of the Balloon Society, held at St. James's Hall, on Friday evening, May 11th, Mr. W. White, F.S.A. (late President of the Architectural Association), in the chair, the following resolution was adopted, moved by Mr. W. H. Lefevre, C.E., seconded by General Brine, R.E., "That this meeting of the members of the Balloon Society deeply deplores the removal by death of Sir Charles Bright, M.I.C.E., the pioneer of transatlantic telegraphy, and desires to record its deep sense of his eminent services rendered to engineering, science and literature, and that this resolution be sent to Lady Bright and relatives."

Chatham. —A local journal says that the local Electric Lighting Company is making good progress, and the engineer hopes to have everything in working order by the end of June. All the shares are taken up, and orders have been received which will absorb the whole power of the plant now being laid down—which is estimated to produce 4,000 incandescent lights of 10 candle-power each. Great difficulty has been experienced in obtaining a foundation for the heavy engine and dynamo on Messrs. Woodhams and Levy's wharf, as beneath the upper layer of made ground a thick deposit of blue clay was met with; this involved a heavy expenditure for piles in order to get a good foundation.

City and Guilds of London Institute.—Old Students' Association.—The next meeting of the Old Students' Association will be held at the Finsbury Technical College, Leonard-street, E.C., on Tuesday, May 29th (instead of on Wednesday, May 23rd, as previously announced), at 7:30 p.m. The following Paper will be read :—"Some Installation Breakdowns," by Reginald J. Jones, A.S.T.E. and E. The author will deal with accounts of breakdowns of plant, faults, &c., in actual practice in connection with—(*a*) "arc" dynamos and driving gear, (*b*) "incandescent" dynamos and driving gear, (*c*) motors, (*d*) arc light circuits, (*e*) incandescent light circuits, (*f*) arc lights, (*g*) incandescent lamps, fuses, &c. A smoking concert will be held early in June, further notice of which will be given.

The Electric Light at Railway Stations.—The question of the electric lighting of railway stations was discussed at the recent meeting of the International Railway Congress held at Milan, and it was stated that installations of this description have much increased of late years. In France, the goods station at La Villette and the St. Lazare terminus are lighted by electricity, while there are partial installations at Paris, Marseilles, Bellegarde, and Lyons. In Germany, forty-six stations are so lighted, Strasburg, with its 70 arcs and 100 incandescents, coming first. In Austria, only four stations possess complete installations. In Belgium there are seventeen stations so lit, and in Italy six. Arc lamps are generally preferred to gas; but in many cases the Lucigen light is employed on account of its cheapness.

The Metropolitan Theatres Bill.—At a meeting of the Balloon Society, held at St. James's Hall, Piccadilly, last week, Mr. William White, F.S.A. (late President of the Architectural Association), in the chair, an address was delivered by Mr. E. E. Marriott (of the Cyanite Fire Prevention Corporation, Chelsea) on "Fire Prevention," at the close of which the following resolution was adopted :—"This meeting is of opinion that the Metropolis Theatres Bill, introduced into Parliament by Mr. Dixon-Hartland, M.P., for the better regulation of theatres and music halls in the metropolis, deserves support, believing that it will secure, under the control of Her Majesty's Secretary of State for the Home Department, greater safety and security for theatres and music halls and all places of amusement and entertainment; and that a copy of this resolution be sent to Mr. Dixon-Hartland, M.P., and a petition, signed by the chairman on behalf of the meeting, be presented to Parliament."

Exeter.—At a meeting of the Exeter Town Council last week, the Exeter Electric Light Company petitioned to be

Digitized by Google

allowed to erect overhead wires.—Alderman Daw asked if the company were properly registered, whereupon Alderman Ellis queried whether Alderman Daw had asked his question as solicitor to the Gas Company, or by virtue of his position as an alderman.—Alderman Daw expressed surprise at such a remark falling from the chairman of the Electric Light Company. He was not there in the interest of the Gas Company, and he thought the imputation should be withdrawn.—The Mayor said the articles of registration were lying at his (the Mayor's) office.—Alderman Ellis said he was under the impression that Alderman Daw was aware that the company was a substantial one, that shares were being readily taken up, and capital subscribed.—Mr. Blackburn pointed out that there could be no question as to the substantiality of the company, seeing that the original projectors spent £1,000 in lighting the streets of Exeter as an experiment.—Ultimately the application of the company was referred to the Streets Committee.

Messrs. Mather and Platt's Dynamo Catalogues.—This well-known firm has issued a new edition of their dynamo catalogue, Part I. referring to the Edison-Hopkinson type, and Part II. to the "Manchester" type. Each of these machines is too well known to require any detailed notice on our part. The machines are well adapted for use as motors, especially where weight is a secondary consideration, and visitors to the Manchester Exhibition last year will well remember the small "Manchester" motor driving a large wall-paper printing machine. The firm also give special attention to slow-speed dynamos for ship lighting, and plant of this type is now in use by the Admiralty. Where space is limited and high-speed engines are not desirable, the Mather and Platt grip pulley and belt-tightening gear is very effective. We also note that the firm are paying attention to the construction of dynamos designed especially for testing and teaching purposes. The "Manchester" machine at the City and Guilds Central Institution will be familiar to many of our readers. The catalogues are prefaced by some interesting and important details of tests carried out upon these machines (chiefly by Dr. Edward Hopkinson), which have already been fully reported in the technical press.

Electric Lighting at the Italian Exhibition.—The Italian Exhibition is lighted by three hundred arcs of 2,000 c.p. nominal, distributed throughout the buildings and grounds, and one hundred glow lamps, fixed in the Welcome Club. The installation is on the Thomson-Houston system, and has been laid down by Messrs. Laing, Wharton, and Down, of 82, New Bond-street, London. There are ten arc dynamos, each of thirty-five lamps capacity, and one glow lamp dynamo, of one hundred lamps capacity. All the dynamos are driven from one counter shaft, running at 250 revolutions per minute, and provided with 4ft. 6in. pulleys, the pulleys on the dynamos being 16in., and the speed 820 revolutions. Motive power is supplied by Davey-Paxman boilers and engines, there being three locomotive boilers, each of 100 actual horse-power, and one compound undertype combined engine and boiler of 40 nominal horse-power. In addition, there is fixed a compound engine of the girder type, of 40 nominal horse-power, running at one hundred revolutions per minute, and driving from an 8ft. 6in. fly-wheel on to a 3ft. 6in. pulley on the counter shaft. There are also two Windsor engines of the inverted compound type, each of 30 nominal horse-power, running at 180 revolutions, and driving from a 5ft. 6in. fly-wheel on to a 4ft. pulley on the counter shaft.

Fatal Thunderstorms in Germany.—Last week several severe thunderstorms occurred in Germany. The papers state that several people have been struck by lightning in villages lying in the Puttbus district. At Guhrow a young man and woman, on their way home from working in the fields, were overtaken by the storm, and both were struck dead by the lightning. The oxen which were following them at a distance of some twenty yards, drawing a cart, were stunned, and lay for some time unconscious. The young woman's skull was split, while only two small blue spots, one behind the ear and one on the breast, indicated how the man had met with his death. In the village of Ruben a woman who was at work in a field took shelter from the storm in a neighbouring wood, and unfortunately met with the same fate. At Alt-Dobeln a tavern was struck by the lightning. The wife of the owner, who was sitting sewing at a closed window at the time, states that the lightning came through the roof, flashed across the room over her head, and dashed against the window at which she was sitting, smashing several panes of glass. It then bounded back into the room, passing between her two children, girls of nine and ten, who were sitting together on a bench, and ultimately left the house through the wall of another room. The children were unconscious for some minutes, probably from fright, as they do not appear to have sustained any injuries from the lightning.

Proposed Central Station at Birmingham.—"We understand," says the *Birmingham Daily Post*, "that there is now on foot a project for applying electric lighting to a limited but important area in Birmingham. Some time ago the Committee of the Old Library, in Union-street, came to the conclusion that, for the comfort of the readers and the preservation of the books, it would be desirable to substitute electric lighting for gas-lighting, provided that favourable conditions could be arranged. They consulted Messrs. Chamberlain and Hookham on the subject—the electric lighting established by that firm in part of the Art Gallery being very satisfactory—and it was found to be perfectly easy to light the library, as desired; but a difficulty occurred as to the provision of the motive power for the production of the light, the committee regarding it as impossible to make room for an engine in any part of the library premises. This difficulty, however, can be overcome by making such provision elsewhere; but in order to justify that expenditure it is necessary that a considerable area should be lighted, on conditions which would ensure to the promoters of the enterprise a sufficient number of lights, and an undertaking for permanent use of them. Having had inquiries from other persons in the neighbourhood of the library, Messrs. Chamberlain and Hookham have marked out a district bounded by High-street, New-street, and Corporation-street, up to Union-street; and have ascertained that from a common centre any building in this area can be conveniently lighted by electricity, provided, of course, that persons using the light are willing to give permission for the necessary connection from house to house. They are now, we understand, taking means to learn how far the tenants of buildings within this area, which includes the library, are disposed to avail themselves of the advantages of such a scheme. Their proposal is to supply the electric light by meter, on conditions similar to those in operation in Liverpool, where a scheme of private lighting, approved by the Town Council and the Board of Trade, is now successfully working, on terms which allow the light to be supplied at from three farthings to one farthing per lamp per hour, according to the number of hours of consumption."

Electric Lighting in the Sandwich Islands.—A transatlantic contemporary, *Modern Light and Heat*, says that "the Thomson-Houston Electric Company has received a very interesting letter from Mr. W. A. Faulkner, Superintendent

Digitized by Google

Government Electric Light Honolulu, regarding the Thomson-Houston plant which has been installed there. No time was lost in setting up the engines and dynamos after their arrival, and on March 23rd the city was illuminated for the first time by the electric light. Honolulu, the principal city of Hawaii, is peculiarly well situated for electric lighting on account of the water supply, which can be easily utilised for generating the necessary power. The station is situated about 2½ miles from the centre of the city, and is about 400 feet above the level of the sea. Water power at the station is derived from 300 foot head, carried through 5,296 feet of pipe 15 inches in diameter, and there is a pressure of 130 pounds to the square inch. This is a part of the city water supply doing work at the station on its way to the reservoir. The power is supplied by a double discharge mining wheel, 20 inches in diameter, making 1,250 revolutions per minute at the pressure above mentioned. This wheel drives two dynamos, both manufactured by the Thomson-Houston Electric Company, one of twelve, and the other of 50-light capacity; the smaller machine carrying its lights on six miles of wire, and the larger one on fifteen. Both machines have worked admirably, and have given from the start every satisfaction. On the 23rd ult., the day of starting, a distinguished company assembled at the station, among whom were her Royal Highness Princess Kialani, heiress presumptive to the throne, and his Excellency L. A. Thurston, Minister of the Interior. The Princess, under the direction of Mr. Faulkner, completed the circuit, and had the honour of lighting the city for the first time with the new lights. The start was most successful, every lamp burning. The scene in the city was very exciting, the streets being thronged with people, many of whom had been waiting some time to see the lights turned on, and all appeared very much pleased at the result. The lights have been lighted every night since, and the installation has been a most successful one in every way. The members of the Government were so much pleased with the operation of the plant that it is more than probable that the present system will ere long be extended."

Report upon Jarman's Electric Tramcar.—We have received a copy of a report upon the Jarman Electric Tramcar from Messrs. Walker and Hyde, consulting engineers and patent agents. No figures are given save some of a very incomplete character relating to the power expended on a single journey. The following are the most important paragraphs:—"The whole of the locomotive machinery is arranged beneath the floor of the car, and comprises two series electric motors, both armatures of which are mounted upon one spindle, a wrought-iron pinion of 12 teeth being keyed centrally upon said spindle, the motion being thus transmitted to intermediate shaft. The motor pinion gears with a mortise wheel of 48 teeth, and a second pinion of 24 teeth, also keyed upon the intermediate shaft, gears with a similar mortise wheel of 48 teeth keyed upon the driving axle of the tramcar. The peculiarity of the gearing lies in the fact that the mortise wheels above referred to are geared with cogs formed of vulcanite fibre, and flanges are extended up to the top of the tooth, the whole being secured by pins passing through the width of each cog at the pitch line, and which are riveted over through the flanges. The motors are arranged so that while one is propelling the car in one direction the armature of the other is rotating freely within the corresponding field, thereby allowing of the free circulation of air for cooling. In this way one motor may be used for the outward journey, and its armature may be cooled while the other motor is performing the return journey. If additional power be required both motors may be used at once. The accumulators being arranged in trays mounted upon wheels and placed under the seats, may be run out through doors at each end upon a suitable truck or platform upon the arrival of the car at the charging depot, and in our opinion the operation of taking out the discharged cells and replacing them by others newly charged could be performed by two men in five minutes. There were 23 persons upon the car, the general structure of which is much heavier than the modern cars of the same rating now being used upon the metropolitan lines, and we consider that the whole system has been well designed and carried out in a practical and efficient manner, and if a charging installation for even two or more cars was laid down, there would be a distinct saving per car mile over the present cost of maintaining a number of horses to perform the same work, and that the system could be worked, even on a small scale, efficiently and profitably."

Professor Blyth on Wind Power for Electric Lighting.—An interesting paper dealing with the production of electricity by wind power was read by Professor Blyth before the Glasgow Philosophical Society the other night. The professor said that as far as he knew the first suggested application of wind power to the production of electricity was by Sir William Thomson, at the York meeting of the British Association, although no doubt the idea was in the minds of many people before then. During last summer Professor Blyth had an opportunity of making a practical experiment. He erected a small windmill for supplying electric light by means of storage cells to a small cottage in the village of Marykirk, where he spent his summer holiday. The windmill was of the old English type, and was erected in the garden. The tower consisted of a wooden tripod firmly fixed in the ground, and strongly braced together by bars of wood. The windshaft stood about 33 feet above the ground, and carried four sail arms at right angles to each other, each being about 13 feet long. The dynamo, an old form of Bürgin, was driven directly from the fly-wheel by means of a rope, and a workable speed was attained even when the windmill moved at a comparatively slow speed. The current from the dynamo was employed to charge twelve electric power storage cells, which supplied the incandescent lamps in the cottage. As yet he had only used at one time 10 eight candle-power 25-volt lamps, but he found that storage for more could be quite easily obtained. One day when a good breeze was blowing he stored as much in half a day as gave light for four evenings of about three or four hours each. As yet, however, he had not had time or opportunity to test fully the capabilities of his arrangement. For one thing, he required a more suitable dynamo and a much greater storage capacity, so as to take advantage of all the wind blowing, and when this was done he had no doubt whatever regarding the complete success of his experiment. While charging, the current passed through a cut-out arrangement, which immediately disconnected the cell from the charging circuit when the dynamo ran below a certain speed. In this way the windmill could be allowed to run day and night, as it would only store when a certain speed was attained, and the cells were effectually prevented from discharging themselves through the dynamo even should it stop. On several occasions he had used the stored electricity to drive a small turning lathe, and he had begun to make a light form of crriage to be driven by the same. In conclusion, the professor jocularly remarked that he preferred wind power to water, because the latter was usually tied up. The landlords, however, had not yet claimed a right over the wind, although a place that had a good draught might come to have a money value. In the course of a discussion which followed, the hope was expressed that Prof. Blyth would continue his interesting experiments.

ON THE INFLUENCE OF SELF-INDUCTION ON THE RATE OF DISCHARGE OF A CONDENSER.

BY DR. OLIVER LODGE.

Mr. Sumpner's letter on page 761 of *The Electrician* for 4th May, 1888, very clearly establishes his statement that the time required for practically complete discharge of a condenser can be diminished in certain cases by inserting in its circuit a moderate amount of self-induction, leaving everything else the same. The point is a curious one, and I congratulate Mr. Sumpner on having noticed it. Anyone would have thought that since the time-constant of a condenser circuit is $\frac{2L}{R}$ an increase in self-induction would have retarded its discharge, and a decrease would have accelerated it. And this is what does happen so long as there is sufficient self-induction to make the discharge oscillatory. Nevertheless, if one proceeds to diminish self-induction still further, the time of discharge begins to lengthen in an unexpected manner, until it is ultimately possible exactly to double the time of a discharge by removing all trace of self-induction from the discharging circuit, supposing this to be experimentally feasible.

One finds that with $L = \frac{1}{2} SR^2$ the time taken over a complete discharge is just the same as when $L = 0$; also that when $L = \frac{1}{4} S R^2$ the time of discharge is just half the preceding, and is then a minimum. This happens to be just the condition when the character of the discharge changes from oscillatory to continuous. The minimum value of the time constant is $\frac{1}{2} S R$, which it has when $L = \frac{1}{4} S R^2$. Altering the self-induction either above or below this value lengthens the time of the discharge, though not in a symmetrical manner; increasing the self-induction above $\frac{1}{4} S R^2$ lengthens the time constant in a simply proportional manner without limit, but decreasing it below $\frac{1}{4} S R^2$ lengthens the time-constant in a parabolic manner towards an upper limit S R, which it attains when $L = 0$.

The following curve shows the whole thing.

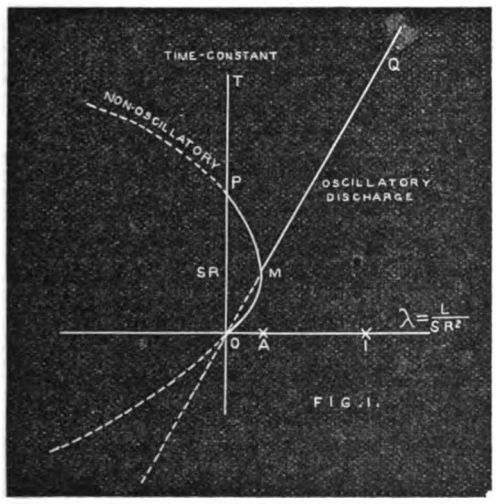

FIG. 1.

Plotted horizontally are successive values of the ratio L to $S R^2$, a ratio which I call λ, and which may be altered by varying the discharging circuit. Unit length is shown by 0 1. Plotted vertically are corresponding values of the time-constant T; viz., the time required for the charge of the condenser to sink from any value to $\frac{1}{e}$th of that value. In a time 2 T the charge is reduced to $\frac{1}{e^2}$, in 3 T to $\frac{1}{e^3}$, and so on.

Now, as e^3 is $(2{\cdot}71828)^3$, or about 20, and e^4 is about 54, it follows that in a time equal to five or six times T the condenser is, for all practical purposes, completely discharged. In a time 7 T only one-thousandth of its original charge remains in the condenser; and in 21 T it is reduced to less than a thousand-millionth.

Hence, if we plot the value of T we represent all we need know as regards the total time of discharge of a condenser or Leyden jar.

The curve consists of two distinct portions. One portion is a straight line, M Q, sloping upwards at the gradient 2 S R vertical to 1 horizontal, and indicating the time-constant of the oscillatory discharge for different values of λ. The dotted part of this line below M has no particular meaning.

The other portion of the curve is a parabola, with axis horizontal and vertex at M, a point characterised by the co-ordinates $\lambda = A O = \frac{1}{4}$, and $T = A M = \frac{1}{2} S R$. This portion of the curve corresponds to the continuous form of discharge.

The height A M represents the minimum time-constant spoken of above, viz., its value when $L = \frac{1}{4} S R^2$. The height O P represents the value of the time-constant (S R) when L is nothing. The most important part of this parabolic curve is P M; the dotted part does not concern us at all, and the bit M O is of small importance, for there are two time-constants to the non-oscillatory discharge; points on M P indicate values of one of them, and points on M O indicate values of the other. The bigger of the two is not only intrinsically more decisive of the time of the discharge, but its term is multiplied by a larger coefficient than the other enjoys. One coefficient always exceeds the other by the amount S R. The smaller one vanishes for $\lambda = 0$. Both become infinite for $\lambda = \frac{1}{4}$.

Theory of the Discharge.

But it now remains to consider what effect the size of these coefficients exerts upon the *rate of discharge*. Plotting the time-constant does not tell us everything, for though it is the value of the time-constant that decides the *ultimate time of complete discharge*, yet upon its earlier stages the coefficients can exert a very appreciable effect, and accordingly conditions which cause the rate of discharge to be at first comparatively slow may ultimately make it overtake its competitor.

One can hardly make this fully clear without writing down the equations.

The equation to the current at any instant during the discharge of a condenser of capacity S is of course

$$L\frac{dC}{dt} - RC = V - V' = \frac{Q}{S} \quad . \quad . \quad . \quad . \quad (1)$$

where Q is the charge remaining in condenser at any time, and $C = -\frac{dQ}{dt}$. This equation contains the whole theory of a discharging condenser, neglecting the static capacity of the discharging conductors, and ignoring the series of facts experimentally observed with certain dielectrics as "residual charge."

It should be well known (perhaps it is)* that Sir Wm. Thomson originally established this equation and worked out its prime consequences in 1855.

Integrating the equation, it becomes

$$Q = Q_0 e^{-mt}\left(\cos n\ t + \frac{m}{n}\sin n\ t\right) \quad . \quad . \quad (2)$$

which in case n is imaginary may be more conveniently written with $n\sqrt{-1}$ for n,

$$Q = Q_0 e^{-mt}\left(\cosh n\ t + \frac{m}{n}\sinh n\ t\right). \quad . \quad (3)$$

where, in either case,

$$m = \frac{R}{2L}; \text{ and } m^2 - n^2 = \frac{1}{LS}.$$

Sometimes it is more convenient to write the equation in the form

$$\frac{Q}{Q_0} = \frac{m+n}{2n} e^{-(m-n)t} - \frac{m-n}{2n} e^{-(m+n)t}. \quad . \quad . \quad (4)$$

It is to be understood that all these four equations are mathematically identical, and express the same series of facts in other words. Sometimes one form is convenient, sometimes another. One can always write the ratio of actual to original

* Since this was written Dr. Fleming's capital expository article on all this appeared in last week's *Electrician*. There is no excuse for not knowing it now.

Digitized by Google

potentials, V/V_0, instead of the ratio of the charges, Q/Q_0, if one so prefers.

Now what we are at present interested in is to see how different values of L affect the rate of decay of Q; especially do we want to compare the rate of discharge with any specified small value of L with the corresponding rate when L is completely abolished—supposing this to be experimentally possible. It is not practically possible to dispense with self-induction altogether, but for the case when a jar overflows its edge, sparking direct from one coating to the other, it is as small as practicable. Perhaps, however, in this case R^2 is smaller still, and so this overflow discharge may be very oscillatory. The easiest way to make L negligibly small is to make R big; it is the ratio $L/_{SR^2}$ which is the vital quantity, the ratio I have called λ above.

Let us for purposes of comparison write down the form of the discharge equation when L is zero. It is very simple, representing a simple logarithmic curve,

$$Q = Q_0 e^{-\frac{t}{RS}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

$\frac{1}{RS}$ may be called the logarithmic decrement; or $\frac{1}{e^{RS}}$ may be called the common ratio of the decreasing geometrical progression formed by the charge remaining in the jar at equal short intervals of time after the discharge has begun; or RS may be called the "time-constant" of the discharge (the meaning of this term being popularly explained above); and this last plan is commonly the handiest. This time-constant for $L = 0$ we may hereafter quote as T_0. $T_0 = RS$.

The time-constant of the oscillatory discharge represented by equation (2) is $\frac{2L}{R}$; while for the continuous discharge represented by equation (3) or (4) there are two time-constants of unequal importance, viz. :—

$$\frac{1}{m-n} \text{ and } \frac{1}{m+n}$$

But in considering the circumstances of the discharge for different values of m and n it is manifest that everything depends on the relation which exists between L and SR^2; hence it will be convenient to write out the equation in terms of this ratio λ.

So written it becomes

$$\frac{Q}{Q_0} = \frac{1+\sqrt{(1-4\lambda)}}{2\sqrt{(1-4\lambda)}} e^{-\frac{1-\sqrt{(1-4\lambda)}}{2\lambda SR}t} - \frac{1-\sqrt{(1-4\lambda)}}{2\sqrt{(1-4\lambda)}} e^{-\frac{1+\sqrt{(1-4\lambda)}}{2\lambda SR}t} \quad . \quad . \quad (6)$$

and it is the time-constants here indicated which are plotted as the parabola in the above figure.

The expression (6) may be made to look a little neater by writing a single symbol, say μ, for the repeatedly occurring quantity $\sqrt{(1-4\lambda)}$; it then becomes

$$\frac{Q}{Q_0} = \frac{1+\mu}{2\mu} e^{-\frac{2}{1+\mu}\cdot\frac{t}{T_0}} - \frac{1-\mu}{2\mu} e^{-\frac{2}{1-\mu}\cdot\frac{t}{T_0}} \quad . \quad . \quad (7)$$

Rate of Discharge from Instant to Instant.

At this point it may be as well to differentiate our equation with regard to t, because it is the rate of decay of Q with which we are specially concerned. We want to see how different values of λ—that is, of L—affect it.

Now, differentiating any of the above equations, except (5), we get

$$C = -\frac{dQ}{dt} = \frac{V_0}{nL} e^{-mt} \text{shin } nt \quad . \quad . \quad . \quad (9)$$

or else the same thing with sin instead of shin; which gives the discharge current at every instant when self-induction is present.

This we have to compare with

$$C' = \frac{V_0}{R} e^{-\frac{t}{SR}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

the value of the discharge current with no self-induction.

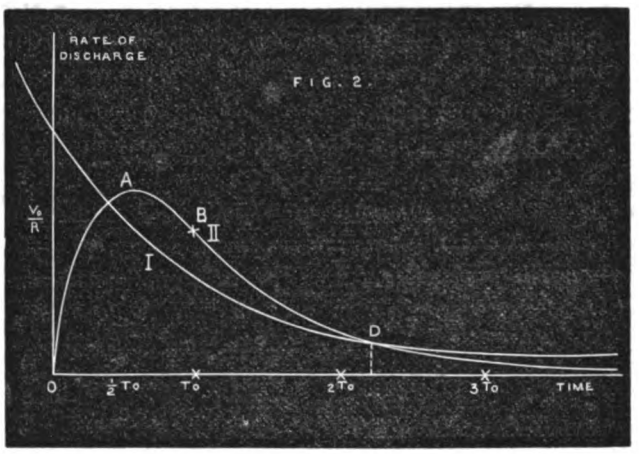
Now the first thing we notice is, that whereas the current without self-induction begins with a maximum value $\frac{V_0}{R}$ and gradually tails off logarithmically, the current with self-induction begins with the value zero and then rapidly increases till it may overtake the other.

The most interesting simple case of (9) is obtained when L is close upon $\frac{1}{4} SR^2$—that is, when $\lambda = \frac{1}{4}$ about; it may be a little bigger or a little less. In either of these cases equation (9) simplifies to

$$C = \frac{V_0 t}{L} e^{-\frac{t}{2\lambda SR}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

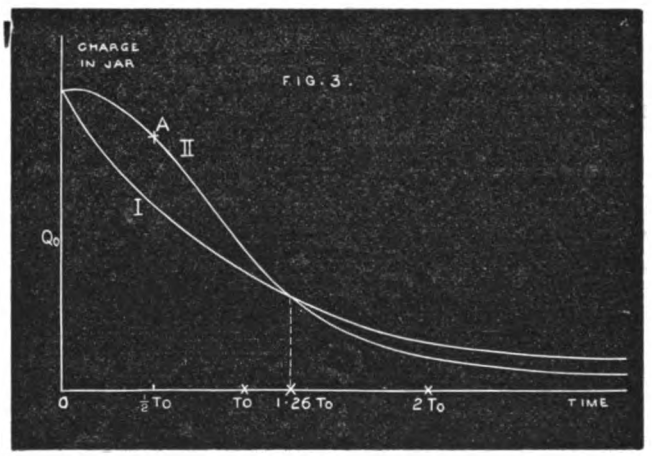
where the thing to notice is the occurrence of t in the coefficient; a coefficient which increases simply with the time. The time-constant is $2\lambda SR$; so if λ were exactly $\frac{1}{4}$ the time-constant in this case would be just half that for no self-induction.

The current at different times for these two cases $\lambda = 0$ and $\lambda = \frac{1}{4}$ are plotted in Fig. 2.



Curve I. represents the strength of the discharge current of a condenser in a circuit of no self-induction. $T_0 = SR$. This curve corresponds to the point P in Fig. 1.

Curve II. represents the strength of the discharge current of the same condenser in a circuit of the same resistance, but with self-induction enough just to bring the discharge to the verge of oscillation, this being the condition which effects complete discharge in the shortest time possible. This curve corresponds to the point M in Fig. 1.



Curve I. shows the charge remaining in the jar at any time, the circuit being practically devoid of self-induction.

Curve II. shows the same thing for $L = \frac{1}{4} SR^2$—that is, for the quickest discharge possible. At first Curve I. has the advantage, but at a time 1·26 RS the second curve overtakes it and discharges the jar more rapidly.

At a time $\frac{1}{2} SR$ from commencement of discharge this current reaches its maximum value; it is then $\frac{2}{\sqrt{e}}$ times the corresponding current for $L = 0$.

At a time SR it is $\frac{4}{e}$ times this corresponding current; and the ratio between them is never bigger than this.

At a time 2·16 SR the two currents are just equal; and after

Digitized by Google

that the inductionless current exceeds the other: ultimately without limit.

These curves show the changes of relative value which the rates of discharge pass through according to the value of the ratio λ; but they do not inform us directly as to which empties the jar first. Let us, therefore, to be quite explicit, plot Q also for the two most interesting cases.

The $\lambda = 0$ case gives a mere logarithmic curve; but the $\lambda = \frac{1}{4}$ case gives an initially horizontal curve rapidly sloping down till it overtakes the other at a point $1{\cdot}26\ T_0$ and then passes below it. At a time $\frac{1}{2}\ T_0$ the charge remaining in jar is $\frac{2}{\sqrt{e}}$ times as great in this case of shortest time of discharge as it is when $\lambda = 0$, but the hurry of the later stages of the discharge more than makes up for the delay of the earlier ones.

Mechanical Analogue.

A pendulum in treacle was long ago suggested by Lord Rayleigh as an analogue to the Leyden jar discharge. The analogy may easily be made exact by considering a loaded spring bent aside or compressed in a resisting medium in such a way that gravity is not concerned with the motion, and then let go.

The pliability of the spring corresponds to the capacity of a condenser, its displacement to the electric charge. The load or inertia corresponds to the self-induction of the circuit; the viscosity of the fluid to its resistance. If the viscosity friction be supposed to vary accurately as the speed, then the equation to the motion is

$$m \frac{dv}{dt} - \mathrm{R}\, v = k\, x$$

where x is the displacement and v is the velocity $\left(-\frac{dx}{dt}\right)$.

Writing m for L, $\frac{1}{k}$ for S, and x for Q, in the electrical equation (1), the two are seen to be the same, and everything we have said applies to the mechanical analogue as well as to the electrical phenomenon.

It is obvious mechanically that if the resistance is moderate and the mass considerable the recoil of the spring will be accompanied by oscillations; also, that with high resistance and small inertia the motion will be a mere slow sliding or leaking back. The resistance may be so great as to amount to actual insulation. Again, it is plain that there must exist between the strength of the spring, the mass of its load, and the viscosity-coefficient R of the substance, some definite relation which shall constrain the recoil to be a simple dead-beat return to the position of equilibrium, without delay and without overshooting the mark. This relation we now see to be

$$\mathrm{R}^2 = 4\, km,$$

and under these circumstances the recovery of the spring is the quickest possible.

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(Continued from page 689, Vol. XX.)

The work of the metropolitan exchanges is chiefly carried on by girls, except at some of the City exchanges which are situated in positions rendering the employment of girls undesirable. The work at these is done by boys, who for the most part continue in the service of the company in some of its various departments. The switch-boards are of various constructions, as is inevitable, owing to the rapid progress which is being made in the technological development of telephony. Improved switch-boards are adopted as they come out in the new exchanges, and are gradually introduced into the older ones. The older forms necessitated the operators calling to each other across the room to make the required connections, leading to a continual noise in the switch room, which was by no means favourable to the rapid and accurate despatch of business.

The multiple switch-board, which is coming into general use in the principal telephonic exchanges throughout the world, obviates all this. Each board is connected with all the subscribers to the exchange, who are thus within reach of the operator sitting at each board, while only a certain number of these can call the operator at any one board. Corresponding to each of the latter is a small shutter, which falls when the subscriber rings his bell and exposes his number. The operator then inquires the number of the subscriber with whom he wishes to be put in connection, and if the latter's wire is not engaged—this being ascertained by a tapping arrangement, which, if the wire is in use, produces a noise in the operator's telephone on touching the terminal—the operator calls the other subscriber, takes up the pair of terminals attached to one of a series of flexible wires placed in front of the board, and by placing one terminal plug in the brass hole in connection with one subscriber's wire and the other in the one connected with the other subscriber's wire, places the two subscribers in communication. We need not say that the whole operation is carried out in very much less time than it takes to describe it.

At each of the trunk exchanges one operator devotes his or her whole time to listening at a telephone in connection with the central exchange, and at the central exchange all the operators listen at their telephones, as no call bells of any kind are used to and from the central exchange. Each operator at the central exchange is furnished with a flexible wire and terminal plug, in connection with a separate telephone fixed in front of his board. When asked for any exchange he ascertains which, if any, of the trunk wires are free by touching their terminals with his plug, which he is supposed to keep strapped to his finger. If any trunk wire is in use a noise is produced in the before-mentioned telephone on touching the trunk terminal with the tapping terminal. The operators at the central trunk exchange are all boys.

For speaking purposes Leclanché cells are used. For calling purposes magneto-generators are now generally used. They are, however, decidedly objectionable when used as vigorously as they often are by impatient subscribers, owing to the large amount of noise which they produce by induction in the neighbouring lines.

The over-house poles and standards are all made of iron, and the networks of wires proceeding from the exchanges are supported on massive constructions built up of iron girders with cross struts and ties, firmly attached to the roof of the building containing the switch room. These constructions are known as "derricks." The wires are of iron, hard copper, phosphor-bronze, and silicious bronze. Where a number of wires are running in the same direction they are made up into cables, and these cables are supported on iron rings passing over iron supporting wires stretched between the standards.

The map which is given this week will show the actual positions of the trunk exchanges whose connections were exhibited in the diagram accompanying our last chapter, and also those of the smaller exchanges actually constructed and in process of construction.

(To be continued.)

JUVENILE LECTURES.

THE APPLICATION OF ELECTRICITY TO LIGHTING AND WORKING.*

BY W. H. PREECE, F.R.S.

Lecture II.

(Continued from page 10.)

I will now show you how electric currents can be used to produce rotation or to produce motion. The history of motors is extremely interesting; it commences in the year 1823, when Mr. Barlow, the father of the present well known engineer, the engineer of the Tay Bridge, and past president

* A course of two Lectures delivered before the Society of Arts on January 4th and 11th.

Digitized by Google

of the Institution of Civil Engineers, showed how it was possible to produce rotation by means of currents of electricity. The great apostle of electricity, Faraday, in 1831, did the same thing; and in 1833, Ritchie produced that very instrument that I showed you; but as far back as 1839 there was a Scotch gentleman, of the name of Davidson, who thought that this principle was applicable to the drawing of trains on railways, and I have a slide, which Mr. Carpenter will now throw upon the screen, showing his locomotive.

You now see a picture of that machine (Fig. 8), as used on the Edinburgh and Glasgow Railway, or rather, I will not say it was used, because I do not think it could have been used, but it was tried on that railway as far back as 1842. You see there were eight electro-magnets, through which currents were

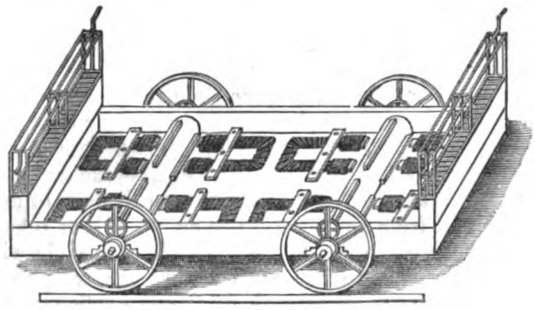


Fig. 8.

passed, and these rotated the wheels. The machine worked at the rate of nine miles an hour. Other distinguished scientists have worked in this direction. Jacobi, of St. Petersburg, about the same time, drove a boat on the River Neva by means of an apparatus very similar to Davidson's. Froment, whose apparatus I showed you, applied this principle to his workshops in Paris; the tools in his shop were worked by an exactly similar motor to that which I showed you just now. Motors are innumerable. I have on the table here models of all the various patterns. Here is a very well-known motor, the invention of an American named Griscom; here is a motor, and I have no doubt if I pass a current of electricity through the electro-magnet of which it is formed you will see that it rotates rapidly and works a fan. I will not dwell much on the various kinds of motors that are used. Mr. Immisch has distinguished himself very much in this direction, and I shall show you several of his motors at work. Mr. Parker, of Wolverhampton, has made one of the prettiest motors (Fig. 9), and

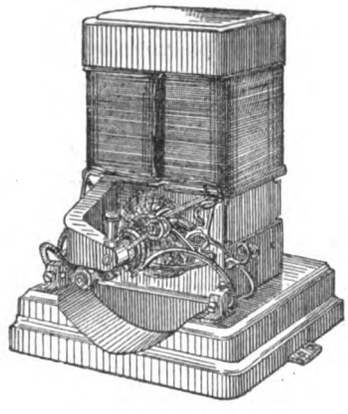

Fig. 9.

I shall show you it also at work. There is nobody who has done more for the practical application of this principle than Mr. Reckenzaun, and I shall show you his motor; and again, Dr. Hopkinson, as well as the house of Messrs. Siemens, have done an immensity to assist this application of electricity.

But I want to illustrate to you the property that the electric current has of transferring power from one place to another. We can produce power in this room, and we could, without difficulty, transfer the power produced here to Liverpool, to Edinburgh, or even to New York. There is absolutely no difficulty whatever in transferring from this very room energy produced by means of the dynamo machine, and sending it if you like to Kamschatka. Of course the amount of energy you are able to transmit is quite another question; the amount varies very much with distance. Telegraphy is entirely dependent on the power which electricity gives us to reproduce mechanical effects at a distance. It would have taken a good deal too much time to have brought before you to-night the various systems of telegraphy. I will show you one, and that one of the earliest and simplest, the old A B C telegraph of Wheatstone. Here is one: it contains a little dynamo machine; when I turn the handle round I am converting the energy of my body into currents of electricity. Currents of electricity are produced by turning the handle, and I am able, by means of little finger keys (similar to the keys of an accordian) placed around the machine, to adjust or arrange the number of currents of electricity that go to the end of the table where the receiving instrument is fixed. As far as the apparatus itself is concerned, it does not matter whether the motor and receiver are separated by eight or ten feet or by eight or ten miles. You can see by this power we are able, in telegraphy, to transmit signals to any distance we like, and at any speed we like. I have mentioned that this power is used for winding clocks, and I will not refer to that again; but this power of transmitting energy to distances is used for a great many practical purposes. For instance, all of you who travel by railway, and I doubt whether anybody here does not travel by railway, are dependent upon this power of electricity to secure safety and to give knowledge of the approach and departure of trains. Sounds can be produced by striking blows, blows being the expenditure of energy, and here I have a bell which is struck by its hammer whenever I send a current through its magnet, and so I reproduce by the current an action similar to that of the elbow. But this same power that electricity gives us to reproduce energy at a distance can be used for purposes which some would be inclined to say are more useful than telegraphy. There may be some people who still look upon a telegram with an amount of horror, and when an envelope containing a message is handed to them immediately turn pale and feel themselves rather affected; but, while many do not care about telegrams, everybody likes water. It does not matter to what class a person belongs he indulges some time or other in water, and any apparatus that will facilitate the production of water will attract our attention. I have here the little Parker motor I mentioned, and a pump. When I send a current of electricity the motor works, and in its turn, by a pulley, works the pump. Mark you, the pump and motor are only a few feet from me, but it would be just the same if they were ten miles away. This simple system of pumping water by electricity is used to a very large extent. There are a great many people who employ electricity now, as I told you at our last lecture, to light their houses, and those who employ electricity to light their houses can employ the same currents and the same power exactly to raise water.

There is a friend of mine near East Grinstead, Sir Francis Truscott, who has his house fitted with electricity. He used to employ two men every day in raising water from a depth of 150ft. to fill his tanks, but when he had secured the use of electricity for lighting his house, I suggested to him that he might just as well use it for raising his water. It was no sooner suggested than acted upon. A little motor, not much larger than that you just saw, works for two hours a day, and supplies a full quantity of water for the house, and the services of the two men were dispensed with in that respect. There is no reason on earth why those people in the country who depend upon manual labour for the raising of water cannot raise their water with greater speed and more efficiency by means of an electro-motor; in fact, this is carried out to a very large extent in South Wales by Mr. Brain. In the collieries in the Forest of Dean electro-motors are used to a very large extent to raise water from depths of hundreds of yards, and through distances that

Digitized by Google

approach from a mile to two miles. Well, the same power exactly that can be used to raise water can be used for many other purposes.

The present Prime Minister of England is a very advanced electrician. There is no man in England who has applied electricity so much for domestic and useful purposes as Lord Salisbury has at Hatfield. He was one of the earliest in the field; he has at Hatfield currents of electricity which are not only used for pumping but also for chaff cutting, turnip cutting, for sawing timber, and for many other farming and domestic purposes.

To-night I am also able to show you this operation of sawing by electricity. The same motion that you saw in raising water we will apply here. Through the kindness of our chairman, Mr. Anderson, we are able to show the arrangement we have here. At one end of the table we have an Immisch motor; it is so small that you can scarcely see it at a distance; it would go in a moderately sized hat, but it will, on a current of electricity going through it, develop three horse-power. It will set a pulley in rotation, that pulley has a strap on it which works the counter-shafting behind me, and from this counter-shafting there are bands that work two or three machines that I shall refer to directly. I now want to call your attention to the circular saw which has been lent us by Messrs. Churchill. Sawing in country houses like Lord Salisbury's is required for cutting up the timber required for fires and for many other purposes, and here we have, by means of this motor, the countershaft and the circular saw at work. Here also is a Singer sewing machine driven in the same way.

(To be continued.)

TELEPHONES IN THE RIVER PLATE.

The last mail from Buenos Ayres brings news of what looks very much like a threatened opposition to the existing companies having exchanges in the Argentine and Uruguayan Republics. Subscriptions were being invited in Buenos Ayres for capital by a new telegraphic-telephonic company of the River Plate (*Compania Telegrafico-Telefonica de la Plata*), the total capital of which was $500,000, in 5,000 shares of $100 each. The Buenos Ayres *Standard*, alluding to the venture, has the following:—

"The promoters of the new company have secured the well-known Van Rysselberghe patent. The importance of this patent cannot be exaggerated, since simultaneous communication can be held on one wire by telegraph and by telephone—a most ingenious contrivance of the Belgian *savant*. The company intend applying this patent to a cable between this city and Monte Video, and it is probable that two cables will be laid down for the purpose under the superintendence of the inventor of the patent."

The Argentines are conspicuous for their use of the telephone. According to official information issued by M. Agustin Gonzalez, the Director of the Argentine Information Office in this country, Buenos Ayres last year possessed one subscriber for every 173 inhabitants, as compared with one for every 865 in Paris, one for every 1,179 in Vienna, and one for every 1,930 in Berlin. From the few details to hand the proposed object and scope of the new company are not clear, except as regards the laying of cables between Monte Video and Buenos Ayres. It is to be hoped that the undertaking does not contemplate competing in the same districts as the existing companies, at any rate for the present. In Buenos Ayres, and in Monte Video more especially, telephone competition has in the past been disastrous. A year last December only, it will be remembered, the prospectus was issued in this market of the United River Plate Telephone Company (Limited), with a capital of £500,000, the object being to amalgamate two companies, namely, that of the United Telephone Company of the River Plate in the Argentine Republic, Uruguay and Paraguay, and that of the River Plate Telephone and Electric Light Company in the Argentine Republic and Paraguay, but not in Uruguay. The aim of this amalgamation was to put a stop to the then existing competition. Further, one of the amalgamating companies—that of the United Telephone Company—was itself the result of an amalgamation of two former companies combined together to fight the River Plate Company. Notwithstanding the popularity of the telephone in the River Plate, it is scarcely likely that the position can have become so changed as to warrant a new competitor when but 18 months ago there were already too many. If, as is possible, the new local company referred to is projected with a view to facilitate intercommunication between the exchanges of Monte Video and the River Plate, shareholders in the existing companies will probably have no reason to complain, and the true interests of telephone enterprise in the Argentine Republic and in Uruguay will not suffer. Nothing is said as to the construction and laying of the cables across the river.

PHYSICAL SOCIETY.

At the meeting of this Society held on the 12th inst. Prof. S. P. THOMPSON read a Paper on

"The Condition of Self-Excitation in a Dynamo Machine."

The author pointed out that as early as 1867 it was known that dynamos possessed the power of self-excitation, and the explanation usually given was that a small amount of residual magnetism remained in the field-magnets, so that when the machine was set in motion a feeble induced current was sent round the magnets. This increased the magnetism of the field-magnets, which in turn produced a stronger induced current. This explanation was even then recognised as faulty, as the limit to which self-excitation went on depended on the resistance in circuit as well as on the speed, and self-excitation did not take place at all for a given speed unless the resistance were below a certain value (for series-wound machines), and for a given resistance it only took place when the speed exceeded a definite minimum value.

In the present Paper the author gives an explanation of the observed facts, that the extent of self-excitation, and also the possibility of self-excitation at all, depend on the speed and on the resistance in the circuit. In a former Paper, in which the author considered the "dead turns" or the conditions necessary for self-excitation to take place at all, the investigation was based on the Lamont-Frölich formula, which is only an approximate representation of the relation between magnetising force and induced magnetism. In the present paper the author makes no assumption with regard to this relation, but merely bases his investigation on the ordinary laws of magnetic induction, with the assumption, however, that the secondary magnetism due to cross-magnetisation may be neglected.

Let N be the number of lines of magnetic force passing through the armature, n the number of revolutions per second, C the number of wires on outside of armature, E the E.M.F. between the terminals, i the induced current, S the number of turns on the field coils, ρ the magnetic resistance, and R the electrical resistance.

Then we have $$E = n C N;$$

and therefore $$i = \frac{E}{\Sigma R} = \frac{n C N}{\Sigma R},$$

where ΣR is the sum of the resistances in the circuit.

Now $$N = \frac{4 \pi S i}{\Sigma \rho},$$

where $\Sigma \rho$ is the sum of the magnetic resistances. Therefore we have the two equations

$$\frac{i}{N} = \frac{n C}{\Sigma R}$$

and $$\frac{i}{N} = \frac{\Sigma \rho}{4 \pi S}.$$

Equating these two values of i/N we obtain

$$4 \pi n C S = \Sigma \rho \, . \, \Sigma R.$$

The product of the magnetic resistance with the electrical resistance will therefore remain constant, provided the quantities on the left-hand side of this equation are unchanged, so that if R be diminished while the speed remains constant self-excitation will go on until, by further magnetisation of the iron, the product is raised to its original value. The dynamo will not excite itself if ΣR is greater than $4 \pi n C S / \Sigma \rho$. Similarly, for a given value of ΣR, excitation is impossible if $\Sigma \rho$ is more than $4 \pi C S / \Sigma R$.

Now, the magnetic resistance is made up of the sum of two quantities, the resistance of the air gap (α), and that of the iron (β), so that $$\rho = \alpha + \beta.$$

Similarly, $$R = a + x,$$

Digitized by Google

where a is the internal resistance, which is a fixed quantity, and x is the external resistance, which is capable of variation.

We have therefore

$$4\pi n \mathrm{C}\,\mathrm{S} = (a+\beta)(a+x).$$

When self-excitation begins β is practically zero, but a has a fixed value, so that when R is very great, self-excitation cannot begin unless the speed is correspondingly high. It is to be noted that the amount of magnetic leakage is neglected, the amount of this depending on the construction of the machine.

Now, suppose the speed to be given, and suppose $\beta = 0$, then, if x_1 be the greatest value of x for which self-excitation can take place, we have

$$x_1 = \frac{4\pi n \mathrm{C}\,\mathrm{S}}{a} - a.$$

Similarly, the greatest value of β when $x = 0$ is given by the equation

$$\beta_1 = \frac{4\pi n \mathrm{C}\,\mathrm{S}}{a} - a,$$

The author pointed out that the constancy of the products $\Sigma\rho\,\Sigma\,\mathrm{R}$ was evident geometrically, for if the curve of magnetisation be drawn by taking the values of the current (i) as abscissæ, and those by the E.M.F. (E) as ordinates, the electrical resistance is represented by the tangent of the angle of slope of this curve, and E is proportional to N and i to S i; so that the magnetic resistance, which is proportional to $\frac{\mathrm{S}\,i}{\mathrm{N}}$, is proportional also to the cotangent of the same angle, and the product of the tangent of an angle into the cotangent of the same angle is necessarily a constant quantity.

For shunt-wound machines, if Z is the number of turns, r_a the resistance of the armature, and r_s that of the shunt coils, the formula obtained is

$$4\pi n \mathrm{C}\,\mathrm{Z} = \Sigma\rho\left(r_a + r_s + \frac{r_a r_s}{\mathrm{R}}\right).$$

If R is increased the quantity in brackets is diminished, so that $\Sigma\rho$ increases, and self-excitation will only take place for a certain minimum value of R depending on the value of the magnetic resistance.

The author mentioned that Mr. Kapp had pointed out the great difficulty in getting small machines to excite themselves. If a model of a given machine could be made with every part reduced in the same proportion it would not excite itself on the same resistance because the magnetic resistance would be greater in the smaller machine, since the reduction in the area of the magnetic circuit would be proportional to the square of the reduction in its length. But everything cannot be reduced in the same proportion, as the air-gap must have a certain value, and the air-gap increases the difficulty of self-excitation.

The author pointed out that according to the results given in the present Paper a dynamo with only a small clearance should have a smaller number of dead turns than one with a larger clearance; but he was not aware that this had ever been noticed.

In the course of his exposition, Prof. Thompson drew the attention of the Society to Mr. Oliver Heaviside's suggestion in the last issue of *The Electrician* of using the term "magnetic reluctance" in place of magnetic resistance, and observed that for his own part he was disposed to adopt it.

Mr. Kapp stated that the subject dealt with in the Paper was well known to the makers of dynamo machines. His own plan was, after using the machine, to get rid of the original condition of the iron, to run the machine at the least speed for self-excitation, and then form the relation

$$\frac{\text{minimum speed}}{\text{minimum voltage}} = \text{constant};$$

and from this and the constructive data of the machine he calculated the minimum value of $\Sigma\rho$, which is nearly equal to a, and he had called this minimum value the critical value of the magnetic resistance. He had always found this critical magnetic resistance smaller than that of the air-gap alone. Prof. Ewing had suggested that this might be due to the copper on the armature, as the copper is counted as forming part of the air-gap, and the magnetic resistance of copper is not the same as that of air. As an example of this, he stated that in the case of a certain machine he had found the critical value of the magnetic resistance between the pole-pieces to be proportional to 1,450 times the double air gap, instead of 1,860 times the double air gap. He had found this difference greater in low-tension dynamos, and this tended to confirm Prof. Ewing's suggestion, as in these machines there was more copper in proportion to the air clearance. A modification was also introduced by the fact that dynamos have a tendency to continue as they are, not to excite or not to fall off when once excited. For example, if a machine were started on a low resistance, say 5 ohms, and would work up to 12 ohms before ceasing to give a current, then the machine would not start on 12 ohms, but the resistance would have to be lowered to 8 or 9 ohms. With a shunt-wound dynamo the opposite effect was observed.

Prof. Perry suggested that this might possibly explain why the air resistance, instead of being represented, as done in Dr. Hopkinson's curves, by a straight line through the origin tangential to the characteristic curve, is really represented by a straight line through the origin intersecting the characteristic.

Mr. Kapp observed that the difficulty of obtaining self-regulation for constant current for an E.M.F. below a certain value was due to this intersection of the magnetic resistance with the characteristic, as the region between the origin and point of intersection was unstable.

Prof. Ayrton said that Prof. Thompson's results could not be directly applied to determine the critical speed and resistance, firstly, because no account was taken of permanent magnetism, which produces an E.M.F. of 3 or 4 volts at ordinary speeds, and, secondly, because a is not a constant, as was assumed. a is not of the nature of a Wheatstone bridge resistance, for two reasons—in the first place, owing to the resistance due to the self-induction of the armature, which is considerable for small currents, and, in the second place, because there appears to be a sort of resistance between the brushes and the commutator, which may possibly be due to jumping. With a large external resistance and small currents he had found this as high as 1,000 ohms.

Lord Rayleigh pointed out that the fact that no current was produced below a certain speed had been very simply explained by Sir William Thomson many years ago. His reasoning was based on Faraday's dynamo, a revolving copper disc touched by conducting wires at its centre and circumference, and he also showed that above a certain speed a state of instability ensues, and ultimately the current decreases without limit. The reason that no definite speed is determined is that the work done against E.M.F. is proportional to the square of the current, and so is the work spent in the circuit, so that the two balance each other. He did not like the term magnetic resistance, as the term resistance was of great use in many parts of physics in cases where there was work to be overcome. In the case of magnetic resistance, on the other hand, there was no work to be overcome. He would be quite ready to adopt the term "magnetic reluctance" if it were generally approved.

Prof. Ayrton stated that he had often found that a dynamo could be made to excite itself at a lower speed than it otherwise would by pressing the brushes against the commutator, showing the existence of the resistance to which he had referred before.

Prof. Perry pointed out, as a mechanical analogy, that centrifugal pumps have to be started at a higher speed than the minimum speed at which they will run when once started.

Prof. Thompson, in reply, stated that he was not oblivious of Sir William Thomson's Paper, which formed the foundation for the study of critical velocity. He had noticed that a machine could often be started by putting on or taking off the brushes, but he was not sure which operation produced the effect. He agreed with Prof. Ayrton that a was not a constant, and had only treated it as such more or less approximately. He thought that the reason that a was not constant was due to the great variation in the magnetic resistance of iron in its lower stages of magnetisation. He thought that the difference observed by Mr. Kapp was due to the fringing of the magnetic field.

Mr. Kapp stated that he had added an amount equal to half the air-space to allow for the fringing of the field.

Prof. Thompson thought he had probably made too small an allowance. In reply to Prof. Ayrton, he stated that the slight residual magnetism would make no practical difference. When the speed was small and the resistance great the dynamo would behave, in fact, like a magneto machine, and the current would only increase very slowly with the speed. The amount of this slow increase would depend on the amount of the residual magnetism, but its effect would be inappreciable after the critical point was passed.

Prof. S. P. Thompson then read a Note on

"The Conditions of Self-Regulation in a Constant Potential Dynamo Machine."

In "Dynamo Electric Machinery" a formula

$$\frac{\mathrm{Z}}{\mathrm{S}} = \frac{r_s}{r_a + r_m}$$

is given as expressing the ratio of the numbers of turns in the shunt and series windings of a compound dynamo. This is on the assumption that there is no saturation within the working limits. As this assumption is not legitimate a correcting factor is necessary. The factor is shown to be the ratio of the average permeability over the whole working range to the permeability corresponding with no external current. The formula is transformed so as to be expressed in terms of the "natural" data of the machine, which, as shown in a previous Paper, can be calculated from its details.

Mr. Blakesley read a Paper, "On Magnetic Lag," which we shall report next week.

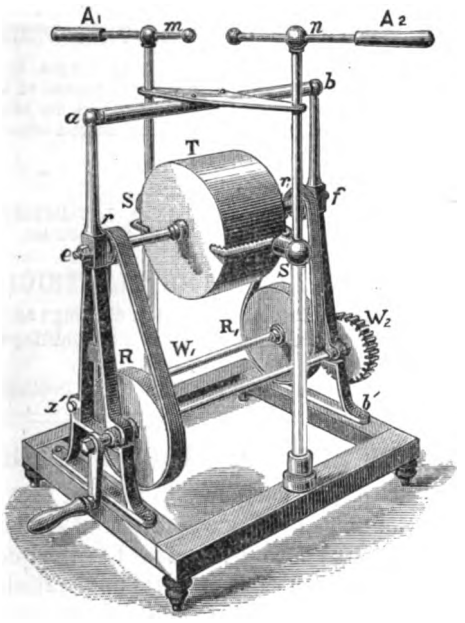
THE GRASER INFLUENCE MACHINE.

A Vienna instrument maker of the name of Graser has recently brought out a new influence machine of somewhat novel construction. This machine, which is chiefly intended to be used to free air from dust and other impurities, is shown in the accompanying figure. The iron supports $a\,a'$ and $b\,b'$ are screwed to a four-legged wooden frame, their tops being joined together by the vulcanite rod $a\,b$. These two uprights support the axles $e\,f$, W_1 and W_2; $e\,f$ is fixed, and is made of steel. Upon $e\,f$ are two vulcanite collars, one of which is joined to the pulley r, and the other to the pulley r_1; at the middle of these two collars are the two ebonite cylinders T, one within the other. In the figure the external cylinder T, communicating with the pulley r, alone is visible. The internal cylinder, which is 8 mm. smaller than the first, is connected to the pulley r_1. The two lower axles, W_1 W_2, each carry a large pulley, R and R_1, and a toothed wheel. The axle W_2 carries in addition the handle M. The pullies r R and r_1 R_1 are united respectively by straps, allowing us to turn r R_1, W_2 and T in the same direction as M, and r R, W_2 and the internal cylinder in the reverse direction. The wooden frame also carries two uprights, which are partly of glass and partly of metal, terminating in the metallic knobs m n. In the middle of these supports are two metallic knobs, S S, each carrying a collecting comb in close proximity to the external cylinder. The fixed steel axle $e\,f$ carries a vertical metal rod inside the cylinder.



The Graser Influence Machine.

At each end of this rod there is a comb, which is at right angles to the corresponding external one. The two exciters A_1 A_2 are movable inside m and n.

The machine requires to be excited by external means.

THE WATER-JET TELEPHONE TRANSMITTER.

At the lecture on the telephone at the Warwick-road schools, Earl's Court, by Mr. G. W. de Tunzelmann, B.Sc., announced in our columns last week, some highly interesting experiments were exhibited.

The United Telephone Company had connected the schools by a special wire to the Gloucester-road Exchange, and from there a connection was established with the Brighton Exchange, where a cornet player had been provided. The audience showed great interest in the transmission of the sounds of the cornet, and of conversation from Brighton, both by means of Edison's loud-speaking telephone, and also by means of a large number of ordinary Bell receivers, which had been provided by the Company, and which were connected in a series of groups with the Brighton line. A number of the early forms of telephones were also exhibited.

Some members of the choir of St. Matthias' Church, to which the schools are attached, sang in the vestry, and the sounds were transmitted to the lecture room by two Blake transmitters, and by Mr. C. A. Bell's water-jet transmitter respectively. This was the first occasion on which the jet transmitter had been tried with Edison's loud-speaking telephone, and the sounds were transmitted with great clearness.

The lecturer illustrated the action of the jet by allowing a simple jet of water from a small orifice to fall upon an india-rubber diaphragm stretched upon the upper end of a vertical brass tube, adjusted at a certain distance from the orifice, this distance being less than that at which the jet became discontinuous. A trumpet-shaped tube was fitted to an aperture in the side of the brass tube close to the diaphragm. When a watch was tightly pressed against the glass tube from which the jet proceeded the jet was thrown into vibration, and the ticking of the watch was reproduced with sufficient loudness to be heard throughout the room.

The jet transmitter, which excited great interest at the *conversazione* of the Royal Society last year, consists of a small jet of water, acidulated to render it a conductor, falling upon two electrodes, consisting respectively of a platinum wire and a platinum ring concentric with the wire, and separated from it by a ring of glass or ebonite. The connection between the electrodes is formed by the nappe of the jet; and when the jet is thrown into vibration by the sound of the voice the variation of the resistance between the electrodes causes it to act as a transmitter of great delicacy. This delicacy is so great that the voice of a person speaking in his ordinary tone at a distance of fifteen or twenty feet from the instrument is reproduced in a distant telephone with the most perfect distinctness. One of the experiments shown by the lecturer was to hold a watch against the sounding-board, to which the jet tube was attached, when the ticking was reproduced in a telephone in connection with the transmitter with sufficient loudness to be heard throughout the lecture room.

The lecture was of a most interesting character, and was listened to throughout with the greatest attention by a large and appreciative audience.

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, May 18th.

ROYAL INSTITUTION.

9 p.m. Lecture, "La Reproduction Artificielle des Roches Volcaniques." By M. ALPHONSE RENARD.

SATURDAY, May 19th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (6). By Mr. CARL ARMBRUSTER.

TUESDAY, May 22nd.

ROYAL INSTITUTION.

3 p.m. Lecture on "Conventions and Conventionality in Art." By Mr. SIDNEY COLVIN, M.A.

ENGINEERING SOCIETY (King's College).

4:15 p.m. Paper on "Harbours." By Mr. COCHRANE.

WEDNESDAY, May 23rd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

Annual Dinner at the Holborn Restaurant.

THURSDAY, May 24th.

SOCIETY OF TELEGRAPH-ENGINEERS.

8 p.m. Extraordinary General Meeting at the Institution of Civil Engineers. On "His New Standard and Inspectional Electric Measuring Instruments." By SIR WILLIAM THOMSON, LL.D., F.R.S.

ROYAL INSTITUTION.

3 p.m. Lecture on "The Growth and Sculpture of the Alps." By Prof. T. G. BONNEY, D.Sc., LL.D., F.R.S.

FRIDAY, May 25th.

CITY AND GUILDS OF LONDON INSTITUTE (Technical College, Finsbury).

7 p.m. Students' Annual *Conversazione*. Lecture on "Polarisation of Light." By Prof. S. P. THOMPSON. And on "Magnifying Springs." By Prof. J. PERRY. Concert and Exhibition of Drawings, Apparatus, &c.

ROYAL INSTITUTION.

9 p.m. On "Personal Identification and Description." By Mr. FRANCIS GALTON, M.A., F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* THE PROPRIETORS.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
,, Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

CONTENTS OF THE CURRENT NUMBER.

THE PORTRAIT OF SIR JOHN PENDER.

To meet the desire of those who wish to frame the Steel Plate Portrait of SIR JOHN PENDER, given with our issue of the 27th April, a limited number of impressions have been taken on large paper, and can be obtained in a neat black and gold or carved brown frame, price Four Shillings each.

Orders to be addressed to—
The PUBLISHER,
"Electrician" Office, 1, Salisbury-court,
Fleet-Street, London, E.C.

VOLUME XX. OF "THE ELECTRICIAN"

NOW READY. Bound in cloth, price Ten Shillings and Sixpence.
Also Cases for Binding, price Two Shillings.

Applications should be made to "The Publisher."

THE FIRE RISKS OF ELECTRIC LIGHTING.

It is difficult to shut one's eyes to the fact that the position which the SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS has drifted into with regard to the question of fire risks and installation rules is a little undignified, not to say ridiculous. To pose as "guide, philosopher, and friend" is excellent when one's counsel is accepted with gratitude and our philosophy is believed in by the admiring crowd; otherwise, as we have said, the attitude leans towards the ludicrous. In the face of so serious a danger no man is better qualified to make the best of things all round than is Mr. PREECE, and everyone will recognise the admirable way in which he has acquitted himself of the task. As regards the rules agreed to by the Committee we are not aware that a word of adverse criticism has yet been uttered, save, perhaps, in respect of the contingent or conditional clauses to which we referred in some detail in our issue of the 13th April. We still think that cases in which it is found necessary to refer to "some suitable material," to "special precautions" (of a wholly undefined character), to certain things which are to be done "if possible," and so on, would be better provided for by an explicit reference to the dispensory power of the Inspector. Mr. ALEXANDER SIEMENS thinks that the rules should be so framed as to draw a perfectly hard and fast line from which the Inspector should have no power to allow any deviation whatever. If this is really in any sense of the word a practicable thing, by all means let it be done. But we think that most practical men will share our scepticism as to its possibility, and in

any case it would involve the redraughting of every rule which contains such phrases as those above quoted. Moreover, we fail to see how the course which Mr. SIEMENS advocates is consistent with the preamble which declares that "these general rules are not intended to supersede any detailed rules which Fire Offices may issue for their own protection."

This leads us at once to the consideration of what is, after all, the *crux* of the position, namely, the attitude of the Fire Offices towards the Society and towards the general question of fire risks from electric lighting. The difficulties of the situation would be greatly simplified if the Fire Offices were themselves unanimous in the matter. Unfortunately, as we all know, this is not the case. We may, however, accept with some degree of satisfaction the assurance of Mr. NEWMAN on the part of the Guardian Office, that one of their chief objects in issuing a set of rules of their own has been to hasten the period when a single code shall be universally accepted. The method adopted is certainly a little ambiguous, but possibly it will, after all, have the desired effect. What it is really important to know is how many of the more influential Fire Offices are really acting with or are prepared to be guided by the Phœnix Office. On this point some very conflicting statements have been made. Mr. CROMPTON stated, and we ourselves have several times received the same assurance, that a very large percentage of the total interest of the Fire Offices recognises the leadership of Mr. HEAPHY; but, however this may be, we suppose it may safely be taken for granted that no absolutely unanimous action on the part of the Fire Offices is to be looked for at the present moment. It is true that there exists a body known as the Fire Offices' Committee, but it is a fact not perhaps generally known that the authority and prestige of this Committee is only of a very limited character. Still, there is no doubt that it forms the best, if not the only, available avenue of approach to the Fire Offices in general, and the Committee of the Council no doubt did wisely in opening negotiations in this quarter. The fact that the preliminary negotiations led to the appointment of a Sub-Committee, who subsequently dealt with Mr. HEAPHY alone, as the representative of the interests of the Fire Offices, may be presumed to imply that the other offices were content to leave the matter in the hands of the Phœnix; unless, indeed, it means that the Phœnix is the only office which takes any sufficient interest in the whole affair; and we should be sorry to think that that is the case.

This brings us to the "personal equation" for which no rational solution has yet been found. It is, nevertheless, impossible to believe after all that has happened that the whole scheme is to be wrecked upon a sentimental point of this character. It is well, however, that the difficulties should be fully and fairly faced, and it is therefore necessary to remark that the question does not entirely lie between the Society on the one hand, and Mr. HEAPHY on the other. It involves also the susceptibilities of those offices who are not willing to recognise any exceptional position on the part of the Phœnix Fire Office. It is impossible to deny that the objection of these dissentients to take any share in advertising a rival is not wholly of an unreasonable character; at any rate, it is rather unlikely that they will be open to argument on this ground. All that can be said is that if these offices are, as we believe them to be, in a minority, then it will be well for the Society to direct its efforts to the establishment of a *modus vivendi* with the Phœnix Office.

In conclusion, writing as we do before the resumption of the discussion on Thursday evening, we have only to add a strong expression of opinion that, if the Committee be reconstituted, it should contain the contracting element in very much larger proportion than it does at present. Three representatives of the contracting interest—of whom perhaps only one is thoroughly conversant with the minute details of installation work—out of a Committee of twenty-three members, even though it included some of the highest professional talent which the Society can boast of, may surely without unfairness be described as a very poor pennyworth of bread to an intolerable deal of sack.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER IX.—*Magnetic Fields.*

(Continued from Vol. XX., page 754.)

106. *The Earth's Magnetic Field.*—If a light rod or strip of steel be mounted at its centre on a horizontal axis so that it is perfectly balanced and free to move in a vertical plane, and it is then taken off the pivot and subjected to the process of magnetisation, it will be found on replacing it in its bearings that it will appear to have one end heavier than the other; that is, the rod will take up a definite inclined position, and will not remain in any other position but this. This effect is due to the magnetic field of the earth, and in our latitude it is the north pole of the pivoted magnet which is so "inclined" or "dipped" downwards. By the exploration of the magnetic field of an ordinary bar magnet (as shown in Fig. 60) it may be noticed that the suspended needle "dips" when near either pole; but when over the centre or equator of the magnet it remains horizontal, and we account for the effects observed on the surface of our globe by imagining its axis to be a huge magnet, whose north pole lies towards the geographical south, and whose south pole lies towards the north. If we shift the position of the magnetised steel rod until it is free to move in a vertical plane *coinciding* with the direction of the magnetic meridian, we have the greatest angle of dip, and the magnetised rod is lying in the direction in which the "intensity" of the earth's field is greatest.

The angle which the rod or needle so inclined makes with the horizontal is termed the angle of "*Dip*" or "*Inclination.*" As we go further north the "angle of dip" increases, and we should expect to find the needle nearly vertical in regions near the geographical north pole. Similarly, on going south the "dip" decreases until there is no dip at all. We are then on the "magnetic equator" of our globe, and this equator, in which there is no angle of dip, runs very nearly through Aden, Madras, Penang, and Borneo, being several degrees north of the geographical equator. Going further south still the needle "dips" the other way—that is, with its south pole downwards, the angle of dip at the City of Melbourne being about the same as in London now—viz., about 67 degrees. At the time it was first observed in the year 1576, it was 71° 50′ in London, and it steadily increased, until in 147 years after that time it had reached 74° 42′, since which it has been slowly decreasing down to our present time.

It is not within the scope of these Papers to describe the methods of taking measurements of terrestrial magnetism; these are continually carried out at the different Observatories, with instruments of great precision, as for example at Kew and Greenwich, and continuous records kept.

The "*Total Intensity*" of the earth's field is the intensity measured in a direction inclined to the horizontal by the angle of dip or inclination, and in the vertical plane of the magnetic meridian. In order to express this total intensity in units of magnetic measurement, or indeed to express the strength of any magnetic field in units, we must first define the unit magnetic pole and the unit of force.

107. *The Unit of Force* on the centimetre gramme-second system is that force which acting on a mass of one gramme, free to move, imparts to it every second an acceleration or increase of velocity of one centimetre per second, or, in other

Digitized by Google

words, that force which acting for one second on a gramme gives it a velocity of one centimetre per second. This unit of force is termed the "*Dyne*," and is equal to about the weight of 1·02 milligramme. If a mass of one gramme were allowed to fall by the action of gravity, the force exerted on it would be 981 dynes, because its acceleration would be 981 centimetres per second every second. Now, all bodies fall at the same rate, from the same height, in vacuo, whatever their mass, since one gramme experiences a force of 981 dynes, two grammes double that force, and so on, the ratio between force and mass being constant; and this ratio is the acceleration due to gravity. Hence the acceleration due to gravity is constant and equal to 981 centimetres per second per second, and the force in dynes exerted on any body in the earth's gravitation field of force is found by multiplying this acceleration by the mass of the body in grammes. As an example of this, take one kilogramme (1,000 grammes): the force of gravitation on each gramme is 981 dynes, and, therefore, on one kilogramme is 981,000 dynes, and it is precisely this force acting on the mass which gives it what we call weight. Again, one English pound is equal to 453·6 grammes, and therefore its weight is equivalent to $453{\cdot}6 \times 981 = 44{,}500$ dynes nearly.

108. *The Unit Magnetic Pole.*—We can now define the unit magnetic pole, which on the C.-G.-S. system is that pole which, placed at one centimetre distance from an exactly similar pole, exerts a force upon it of one dyne. Here we have a measurable quantity, and having established the unit pole, we can measure the strength of any pole in C.-G.-S. units by the force it exerts on a unit pole placed at one centimetre distance from it. Coulomb established by means of his torsion balance, described in most text-books, the law of inverse squares with reference to magnets—that is, that the force exerted between two magnetic poles varied directly as the product of their individual strengths, and inversely as the square of the distance between them. If two magnetic poles, when placed five centimetres apart, experienced a force of four dynes between them, we should know that the product of the strengths of the two poles was equal to $(5)^2 \times 4 = 100$, and if the strength of one of the poles was equal to unity, the other pole would be 100 units in C.-G.-S. measure. In that case the unit pole would be acted upon by a force of four dynes, due to a magnetic pole of strength of 100 units placed five centimetres away. In other words, the unit pole would be in a magnetic field equal to four C.-G.-S. units; this brings us to unit magnetic field.

109. *Magnetic Field of Unit Intensity.*—In the C.-G.-S. system the unit magnetic field is that field which will exert a force of one dyne on a unit magnetic pole placed in it, so that when we speak of a magnetic field of so many C.-G.-S. units it means that a unit magnetic pole placed in it would experience a force equal to that number of dynes. Sometimes a field is expressed as equal to so many dynes; this is a careless and incorrect way of expressing it, what is meant being that the field would exert that number of dynes force on a unit pole. There is no name given to the unit magnetic field, so that the strength of a magnetic field is simply expressed as so many C.-G.-S. units. It is also assumed that the number of lines of force per unit area (the area being at right angles to the direction of the lines) is a measure of the intensity of a magnetic field, and the unit intensity of field is taken as one line of force per square centimetre area. This assumption is a very convenient one for working out problems in magnetic fields. Suppose we mark a line due east and west on a table, and mark a certain point on the line. Now let a long bar magnet be laid on the line, one pole being at four centimetres distance from the fixed point. Consider the intensity of magnetic field at the point, due to the nearer pole of the magnet. Taking the strength of the magnet pole to be 80 C.-G.-S. units, the intensity of field at the fixed point would be $\frac{80}{4^2} = 5$ C.-G.-S. units, because if we could place a free pole of unit strength at the fixed point it would be acted upon by a force equal to five dynes. The intensity of field at this point could also be expressed by the density of lines of force, viz, five lines per square centimetre. We are here supposing the magnet to be so long that we may neglect the action of the other pole. If, now, a short magnetic needle, such as a small compass needle, was placed so that its centre exactly covered the fixed point, and in a line at right angles to the bar magnet, there would be a force acting on each pole tending to turn it about its centre. If the strength of each pole were 10 C.-G.-S. units, there would be a force of $5 \times 10 = 50$ dynes at each end of the needle acting in opposite directions, and therefore tending to move the needle about its centre. Now the needle has been placed in the magnetic meridian, and therefore is parallel to the horizontal component of the earth's field, which would be ·18 C.-G.-S. units. This field would therefore act on each pole of the needle with a force equal to $\cdot 18 \times 10 = 1{\cdot}8$ dyne. Now, if we freely suspend the needle horizontally about its centre it will move through a certain angle, depending on the resultant of these two forces.

We need only consider one end of the needle to find the angle through which it will be deflected from the meridian and the two forces acting at one end are at right angles to each other. Therefore, by the parallelogram of forces, it is evident that

$$\frac{\text{force due to bar magnet}}{\text{force due to earth}} = \text{tangent of angle of deflection;}$$

that is, $\frac{50}{1{\cdot}8} = 27{\cdot}7 = \tan \text{ of } 87°56'$.

The needle would therefore be deflected nearly 88 degrees from the north and south line, and would lie in the *direction* of the resultant force.

Similarly, by the parallelogram of forces, we may find the *amount* of the resultant force, the ratio being

$$\frac{\text{force due to bar magnet}}{\text{resultant of both forces}} = \text{sine of angle of deflection;}$$

whence

$$\text{resultant force} = \frac{50}{\sin 87°56'} = \frac{50}{\cdot 99934} = 50{\cdot}034 \text{ dynes.}$$

The intensity of field, or number of lines of force per square centimetre in the direction of the resultant force, will therefore be

$$\frac{\text{resultant force}}{\text{strength of needle pole}} = \frac{50{\cdot}034}{10} = 5{\cdot}0034 \text{ C.-G.-S. units.}$$

The field, in this case due to the magnet, is so much more powerful than that of the earth that it is practically equal to the resultant.

It will now be understood what is meant by saying that the total intensity of the earth's magnetic field is equal to ·47 C.-G.-S. units. The total intensity of the earth's field does not come into the calculations with galvanometers, since the needles are not used pivoted in the angle of dip; but the needles of galvanometers being horizontal, they are acted upon by the horizontal component of the earth's total magnetic force, usually denoted by the letter H. It is evident that, knowing the value of the total force of the earth in the direction of the dipping needle, and the angle of inclination which this force makes with the horizontal, we can resolve it into two component forces, one acting horizontally, the other vertically.

Resolving it, we have the

horizontal component = total intensity × cosine of angle of dip.

Thus in the year 1879 the total intensity in London was ·4736 C.-G.-S. units, and the angle of dip was 67° 42′. From this we get the horizontal component

$$= \cdot 4736 \times \text{cosine } 67° \ 42'$$
$$= \cdot 4736 \times \cdot 37945 = \cdot 1797 \text{ C.-G.-S. units.}$$

Similarly resolving for the vertical component we have the

vertical component = total intensity × sine of angle of dip.

Therefore for the same year the vertical component was

$$= \cdot 4736 \times \sin 67° \ 42'$$
$$= \cdot 4736 \times \cdot 9252 = \cdot 4381 \text{ C.-G.-S. units.}$$

The value of the horizontal magnetic field of the earth is on the increase, and is now equal to ·18 unit in London, while the total intensity is decreasing gradually in value.

(*To be continued.*)

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

WEDNESDAY, MAY 9TH *(continued)*.

Examination of Mr. BERNARD PROCTOR resumed by Sir HORACE DAVEY: I saw numerous lamps during the period referred to. Those lamps were made partly by Mr. Swan and partly by Mr. Stearn, Swan supplying carbon and Stearn exhausting and mounting. I saw them at Bell's-court and Moseley-street, in Newcastle. All those were vacuum lamps. They were all incandescent lamps, with platinum wires sealed into a glass bulb exhausted of air, and carbon conductors. As far as I remember those lamps contained carbon, some made from paper and some from thread. Some would have thicker ends at the union with the platinum than others. The carbons varied in thickness, but thinness was aimed at. They were all much thinner than the pencil carbon used in the original lamp F I B 1. The shape of the carbon conductor was arched or horse-shoe, not looped. Most of them were simple horseshoe. I saw some of these carbon conductors before they were put into the lamp, and had them in my hands. I do not think any of them were shown by Mr. Swan at his lectures prior to 1879. I am an experienced chemist. I know from Mr. Swan how some of these carbons were made; from my own knowledge I do not know, as I never prepared them, and have no personal experience. I should think as a scientific man it is perfectly impossible these carbons could have been cut by a saw and file out of a gas retort. I saw these lamps running frequently during the period mentioned, sometimes singly, sometimes as many as twenty at a time. When two or three were burning together they did not all burn with the same luminosity. I always supposed that arose from the difference of thickness in the carbons and varying resistance. As individual lamps, many of them would be about 10 to 12 or 14 candle-power. I remember Mr. Swan having a gas engine erected at Moseley-street. That was in the spring of 1879. It was for working his dynamo. I remember an alteration being made in the fly-wheel of the engine, but cannot fix the date. The lamps burned a little unsteadily, and the alteration was made in the hope of securing greater steadiness of light. My impression is that that took place in 1879. The carbons I saw in the lamp at Mr. Swan's establishment would in all probability represent the carbons I saw prepared to be put in the lamps. I also saw at the Post Office, Newcastle, lamps made by Swan burning. That was in Mr. Heaviside's room. The lamps at Moseley-street had thin strips of carbon from a material cut before being carbonised. Some would be one-tenth to one twentieth of an inch wide, and about one fiftieth of an inch thick, in the form of a strip; others much smaller, not so wide, none thread-like. In point of size, they were very similar to, but rather smaller than, the carbon in J I 3, one of the lamps made by Mr. Gimingham when, as he said, following Edison's specification. I believe the lamps were all exhausted by a mercury pump known as the Stearn pump. I never witnessed the exhaustion of any of them, but I have seen the pump. At Moseley-street I, of course, saw the staff of Swan's assistants and workmen, altogether about 20 men. I also met several of Mr. Swan's relatives at Moseley-street, and occasionally strangers. I remember seeing Mr. Swan's sister, his brother-in-law, Prof. Herschell, and many others it is difficult to name. From time to time I have seen a great many friends of Mr. Swan at the establishment, but I cannot mention them individually. Certain points I saw at the works I understood were secret and in confidence, others I knew were public matters. As to the lamps I saw, Mr. Swan said nothing to me about them being secret or shown in confidence. So far as I know, and from my personal observation, so far as seeing and examining the lamps were concerned, no mystery was made of them by Mr. Swan.

Cross-examined by the ATTORNEY-GENERAL: I was Mr. Swan's partner as Swan and Proctor, chemists, about 1879. I have known Mr. Swan about forty years. I was in 1879 one of Mr. Swan's most intimate friends. I have no recorded memorandum of the dates on the lamps of which I have spoken. I trust to memory as my guide. I was examined at the last trial. I met Mr. Stearn, I think, in 1879, but I am not certain. I knew Mr. Stearn after he came to Newcastle. I probably saw him at Mr. Swan's house at that date. He resided at Rock Ferry, near Birkenhead.

When were you first asked about those dates and the lamps you saw by anybody on behalf of the Brush Company?—At Christmas, about five months ago.

Did you not know perfectly well through the whole of the year 1879 that Mr. Swan was experimenting with reference to incandescent electric lamps, and intending to patent his dicovery if possible?—I believe Mr. Swan intended to do so, but that is not positive knowledge on my part.

Had Mr. Swan any Sprengel pump at all at that time?—I think he had.

Will you undertake to say that prior to the beginning of 1880 Mr. Swan had any Sprengel pump at all?—I could not say positively.

Had he any glass-blowing apparatus which would blow these bulbs, or is it not a fact that during 1879 he had no glass-blowing machinery fit to blow the bulbs of incandescent lamps?—I think that is so.

Is it not a fact that all through 1879 Mr. Swan was sending carbons to Mr. Stearn to be put into lamps, to have the glass for them, and to be exhausted?—I have already stated that so far as I understand that is what took place.

Did not Mr. Swan tell you in October, 1879, or thereabouts, that he was afraid Edison would anticipate him?—I do not remember. I will not say he either did or did not.

Do you remember being shown a letter in which Mr. Stearn referred to Edison's experiments as reported in *Nature* and the *Mechanic* in October, 1879?—I do not remember.

Did it not come to your knowledge before the end of 1879, about November or October, that Edison was supposed to be working on the same lines as Swan?—Yes; it came to my knowledge that he was working on similar lines.

Do you not remember this passage being either read or shown to you in a letter of 3rd October, 1879, from Mr. Stearn to Mr. Swan:—"Have you seen the account of Edison's experiments in vacuo in this week's *Nature* and the *Mechanic*? He has trodden so closely on our ground that if he has patented his process I am afraid he has anticipated you entirely." Does not that bring back to your mind that you were told by Mr. Swan in October, 1879, that Edison might have anticipated him?—I cannot say I remember that.

Did not Mr. Swan tell you that as far as Edison's experiments or trials were concerned he did not mention carbon?—I do not remember that.

Did you ever see a lamp exhausted or glass blown in Swan's premises until the Christmas of 1879?—I cannot undertake to say so. My impression was that they were all blown at Birkenhead at that date.

Did you see several lamps that came back from Mr. Stearn in the year 1879?—Yes.

With a very few exceptions had not every lamp sent up by Mr. Stearn got the carbon conductor broken?—I know a great many carbon conductors were broken; I cannot say what proportion. I had no record at that time.

Had some of the lamps which came back from Mr. Stearn copper coils inside the bulbs between the glass and the carbon?—I do not remember copper coils.

Had they platinum caps?—I do not know that any of them had platinum caps. I remember the caps being made, but cannot give the date.

Shown lamp and asked—Did you see one or more lamps similar to that in the year 1879, after it came back from Mr. Stearn?—I do not remember having seen such.

Did you learn from Mr. Swan in December, 1879, that he thought Edison had been working on carbon?—That would be the date at which he learned Edison had been working on carbon, through a letter in the *Daily News* copied into the *Pharmaceutical Journal*.

Do you remember Mr. Swan, at or about Christmas, asking you if you had seen the letter in the *Daily News*?—I know we talked about it.

Did Mr. Swan tell you, about Christmas, 1879, that he was afraid Edison had been working carbon?—I have no doubt that something of that kind occurred.

Were not some of those lamps which Mr. Swan showed you lamps in which there was carbonised paper?—I believe some of those lamps which Mr. Swan showed me were of carbonised paper.

Mr. JUSTICE KAY: Tell me what you knew?—That Mr. Swan was hoping to obtain an electric light on the incandescent principle in which he proposed to use carbons made from vegetable parchment.

Do you know where the carbons came from that were sent to Mr. Stearn?—I believe Mr. Stearn prepared them himself.

Did you not know that Mr. Swan was getting his carbons which went to Stearn from Carré?—I think he told me that he got his carbons for the pencil lamp from Carré.

Was not the great difficulty experienced by Mr. Swan experienced in getting the platinum attached to the carbon?—I knew there was great difficulty.

Mr. A. W. HEAVISIDE, examined by Sir HORACE DAVEY, said:—I am superintending engineer of the Postal Telegraphs at Newcastle, and have held that place for 18 years. I knew Mr. Joseph Wilson Swan in the years 1878-9, and had conversations with him on the subject of incandescence and electric lighting frequently. I was in the habit of meeting him now and then. He was interested to talk to me about telegraphs, and I was interested to talk to him about the Swan lighting. I was two or three times at his establishment in Moseley-street in 1879. Mr. Swan asked me to do some work for him. On a few occasions he came to my battery room in the second half of 1879. He appeared to be in a difficulty as to what power he was using in lighting his lamps by means of whatever apparatus he might have at hand, and I was able to tell him approximately by certain tests the amount of current he was using, and also the resistance of the lamps when cold. I think it was matter of conversation that in order to make his lamps successful it was necessary to make his filaments as thin as possible, and of as high resistance as possible. Occasionally Mr. Swan would come to my battery room with a lamp, and I would join up certain bichromate batteries with these lamps for the purpose of running, and we would observe the effect with a given power. That was to find out what current was necessary to illuminate those lamps in a satisfactory manner. Those lamps were bulbs of glass fitted with horseshoe filaments. The conductors were then alike.

The Court adjourned at four o'clock.

THURSDAY, MAY 10TH.

The examination of Mr. A. W. HEAVISIDE was resumed by Sir HORACE DAVEY.

Witness said: Of the carbons I saw there were two classes. In one kind the line of light was even, while in the other kind, if you looked at them from one angle the line of light was finer than if you looked from the right angle. I tested Mr. Swan's lamp on several occasions prior to November, 1879, frequently in presence of friends of Mr. Swan and my own friends. Other persons were present whose names I cannot recall, and in addition to that there was at least one of my staff always present. When I commenced these tests I had loose wires run from the various batteries to the point where we placed the lamp. These loose wires were very inconvenient for making changes in the arrangements of the batteries, therefore I had a test-box put up of a simple character

Digitized by Google

to enable these tests to be made more conveniently. This test-box was put up prior to November 15th, 1879. I remember that, because on November 15th, 1879, I opened a class, and gave my first lecture. That enables me to fix the date. Mr. Swan did not say anything about treating these communications as confidential, neither did that seem to be necessary, because there was general conversation in the Chemical Society as to the proceedings of Mr. Swan. In the latter half of 1879 I had no request for secrecy.

Cross-examined by the ATTORNEY-GENERAL: At the time I speak of I was in the employment of the Post Office, with a staff of from 40 to 200 under me. I was not paid by Mr. Swan at all; everything I did was done as a friend. Witness was here asked to draw on a piece of paper a horseshoe and the lamp round it as he remembered them at the beginning of 1880. On being asked to draw others, such as he saw in 1879, he said he could not do so, as the one he had drawn was simply a type.

Cross-examination continued: I continued to work for Mr. Swan during the greater part of 1880. In the year 1880, I saw at Mr. Swan's establishment at Moseley-street a very large number of lamps of that kind. They were being worked by his dynamos and gas-engine. Some of them had a second coil in the horseshoe. I am not sure whether I ever saw a coil in the horseshoe before December, 1879. In 1879 I knew nothing whatever about the manufacture of the lamps. I did not know if Mr. Swan had any glass-blowing apparatus in 1879. I had heard the name of Mr. Stearn. I did not know he was asking for Mr. Swan. I can only tell you from Mr. Swan's information what the carbons were made of in 1879; I understood from him it was parchmentised paper in some form or other. All my experiments were made with bichromate batteries, chosen because they were the most suitable I had. The maximum pressure put on in 1879 was about 120 volts. I did not know in the end of 1879 that Mr. Swan was hoping to patent an improved incandescent lamp. That was never referred to by him directly or indirectly. I do not remember the date of Mr. Swan discovering or inventing the thread lamp. I believe it was brought to me in the beginning of 1880. I tried the resistance of the thread lamp in the same way as the others. There was higher resistance. Of the twelve lamps I tested, the highest resistance would be not more than 24 ohms. The minimum resistance would be very difficult to remember. Of those twelve none of them had copper coils inside the glass bulbs. I did not see lamps with platinum caps in 1879. [Shown B S P 3.] I never saw such a lamp as that in my life. I discussed with Mr. Swan why the lamps I examined broke down. One specific case occurred in 1879. The specific point was the difficulty of connecting the carbon with the platinum. I cannot fix the dates on which I saw the lamps at Moseley-street before November, 1879. I knew the lamps brought to me were vacuum lamps. I always thought Mr. Swan was earlier than Mr. Edison in the use of threads for his carbons or filaments. In the end of 1879 the name of Edison cropped up frequently, as he inundated the country with communications as to what he was doing.

Mr. GEORGE HOWARD PATTESON, examined by Mr. GRAHAM, said: I am an earthenware manufacturer at Gateshead. I originally served my apprenticeship with Mr. Swan as a chemical and scientific apparatus dealer. I was with Mr. Swan from January 7, 1876, to January 16, 1880, and after that as an assistant till June, 1880. My father at that time was a manufacturer of pottery, and had ovens for baking the pots. Mr. Swan gave me small crucibles, requesting me to get them put through my father's furnaces, and bring them back to him, which I did. They were put through the furnaces with the earthenware in the ordinary process of manufacture. After they had been through the furnaces they were brought to my father's house, and I took them to Moseley-street, and gave them either to Mr. Swan or Mr. Mayfield, the manager. I am not perfectly clear whether I saw Mr. Swan pack a crucible, but I am perfectly certain I saw him unpack at least one after it had been baked. I saw Mr. Swan take from that crucible small strips of what had apparently been, and what I was given to understand had been, small strips of paper, which strips were wrapped in paper, and packed in powdered charcoal. I took at least half-a-dozen crucibles to my father's works. The pieces were of varying widths, from $\frac{1}{8}$th of an inch to $\frac{1}{16}$ths or $\frac{1}{4}$ of an inch, and in length about $1\frac{1}{2}$ or 2 inches. I took some of these crucibles to be fired prior to October or November of 1877. The heat in the particular furnaces in which the crucibles were fired was raised very slowly, taking 24 hours to reach a dull red heat, after which it was carried to its highest degree. I remember Mr. Swan trying some experiments with electric lamps in a room in which I worked—testing the light and exhibiting it to others. I can only fix the date by reference to Mr. Swan's public lecture. The lamps which I refer to as being exhibited in the chemical room were exhibited prior to Mr. Swan's first lecture in January, 1879. The shape of the conductor in the lamp I refer to was straight. It was from 1in. to $1\frac{1}{2}$in. in length. The conductor was flat in one case, in another the conductor was also straight, but the section was circular. The lamps were incandescent for varying lengths of time up to several minutes' duration. The platinum wires were fused into the glass. [Shown F I B 1.] One of the lamps I saw resembled this, and the other had the flat burner I referred to but otherwise resembled this. During the time the lamps were being tried in Mr. Swan's works several persons were present, amongst others Mr. Proctor, Sir William Armstrong, Prof. Herschell, Mr. John Patteson, and others. Besides those gentlemen the staff were present. I heard no instructions as to secrecy. I was present at the lecture on the 3rd of February, 1879, and remember Mr. Swan exhibiting a lamp on that occasion. The lamp at the lecture burned thus—the burner became heated to red heat, giving nothing like the light that incandescent lamps do now. I remember a gas engine being put up at Mr. Swan's works. It came to Moseley-street on 3rd or 4th March, 1879. Between that date and the date of Edison's patent, November, 1879, I saw Mr. Swan experimenting with some other lamps in the late summer of 1879. The bulbs of these lamps were a good deal more rounded than the earlier ones, and somewhat resembled a radiometer in shape. [Witness here, at the request of counsel, made a sketch of the lamp.] He then continued: I saw more than one lamp of this sort during the interval we are speaking of. They burned fairly satisfactorily, and I do not remember any as having broken down.

Cross-examined by Mr. ASTON, Q.C.: I was with Mr. Swan during a portion of the year 1880. During that year I did not know that Mr. Swan took out two patents at that time. I will pledge my memory that there were no lamps tried in my presence after January, 1880. In 1880 I had control of the chemical room and most of the apparatus stock. I saw the lamps of which I have made a sketch tried in the engine room.

Mr. JOHN THOMAS MAYFIELD, examined by Mr. GRAHAM, deposed: I am an electrician, carrying on business in Queen Victoria-street, London, and was formerly manager at Mr. Swan's works in Newcastle. I was with Mr. Swan from April, 1874, till October, 1879. I was manager of the scientific apparatus department. I remember Mr. Swan carrying out experiments with electric lamps. That lamp was in use in the months of October and November, 1870. The conductor had been made from carbonised paper. Other lamps were being made by Mr. Swan at that time with various conductors. Mr. Swan experimented in every direction, so that anything that could be carbonised would naturally be there. I remember Prof. Herschell, Sir William Armstrong, Mr. Barker, Mr. Proctor, and Mr. Patteson seeing the experiments. I remember Mr. Swan delivering lectures at Gateshead and Sunderland. I believe he there exhibited the same lamp as at the Literary and Philosophical Institute. My impression is that as soon as Mr. Swan had described the incandescent lamp and turned on the current it was allowed to remain on during the rest of the lecture at Sunderland. That would be from a half to three-quarters of an hour.

Mr. JOHN RIDLEY, examined by Sir H. DAVEY: I am a mechanical and electrical engineer at 25, Newgate-street, Newcastle-on-Tyne. I am acquainted with Mr. Joseph Wilson Swan, and have done work for him, first on the 5th March, 1879, in Moseley-street, Newcastle. The work was erecting an Otto gas engine and various other work, such as fixing dynamos, wires and other things not connected with electric work. The wires were fixed for running lamps. I fix this date, 5th March, by my day book, into which entries were made by me at the time. On the 5th March, I received the engine from the North Eastern Railway Company. The dynamo machine was at work on April 5th, 1879, or thereabouts. I cannot tell when it was first at work. The dynamo was then driving lamps. I was frequently, during the year 1879, at Mr. Swan's place at Moseley-street. I saw the dynamo at work many times. It was driving lamps. I saw the lamps burning. Other persons were present at the time, such as Mr. John Cameron Swan, Mr. Proctor, and Prof. Herschell.

Cross-examined by the ATTORNEY-GENERAL: Will you pledge your oath that you ever saw a horseshoe lamp with a loop before the year 1880?—I never saw a lamp without a loop until I came to the Electric Exhibition in the Crystal Palace.

Will you pledge your word that you ever saw a lamp with a loop at Mr. Swan's until the beginning of 1880?—I did.

Cross-examination continued: I do not know the material that the first loop lamp Mr. Swan made was composed of. In the latter end of 1880 I heard that the carbon for Mr. Swan's lamp was made of thread. I have nothing beyond the book produced to enable me to state the number of days I went to Swan's. I was not there at all between 24th May and 23rd October, 1879. From the book I can swear that I was at Mr. Swan's on April 5th and May 3rd. I have seen the dynamo run for transformer or induction experiments many times. I did not know where Mr. Swan was getting his lamps from in the year 1879.

Mr. WM. MENZIES, Mr. CHAS. BLACKBURN, and Mr. JOHN LANG gave evidence of a similar character to that of the last witness.

The Court adjourned at 4 o'clock to meet again on Monday at 10:30.

[———

MONDAY, MAY 14TH.

Mr. EDWARD WILLIAM TURNER, examined by Mr. FINLAY, said: I am second-class superintendent of the Liverpool Telegraph office, and reside at Rock Ferry. I resided there in the year 1878-9. At that time Mr. Charles Henry Stearn was a neighbour of mine. I had communication with him on the subject of electric lamps and electricity. He had a work room in his house. I have been present in that room and have seen him running lamps. The first one I saw was in the summer of 1879. I saw two or three lamps being run during that year at Mr. Stearn's house. These were shown to me about the months of July or August. The first lamp I cannot describe, as it was in a dark room. The second I remember Mr. Stearn holding up to the light for me to see. It was a simple loop of thread formed like a bow. It was enclosed in a globe-shaped glass with a stem and a kind of a point on the top, the connections of the burners being down the stem. I have seen people at Mr. Stearn's house looking at the lamps. I was never told to keep secret what I had seen.

Cross-examined by Mr. ASTON: The first lamp I saw at Mr. Stearn's was in the summer of 1879. I saw other lamps at subsequent periods extending to November, 1880. From time to time during that period Mr. Stearn showed me the lamps upon which he was experimenting. I can only describe the thread of the lamp I saw as like shoemakers' wax.

Mr. JOHN ALLAN, examined by Mr. FINLAY, said: I am battery man in the Liverpool Postal Office. I remember being introduced to Mr. Stearn by Mr. Turner in 1879. I fitted up batteries at Mr. Stearn's house. I remember seeing electric lamps there. The lamp was pear-shaped, with a carbon burner having a thread-like appearance. The burner was the shape of a horseshoe, and appeared to be as thick as a sewing thread. I could not say how many of the lamps I have seen, as they were packed away in a box as soon as tested. I daresay I have seen half a dozen of them. I have seen them burning when being tested. Many people besides myself saw those lamps at Mr. Stearn's. Nothing was ever said

Digitized by Google

about keeping secret what I had seen. It would be in August, 1879, that I saw those lamps.

Cross-examined by Mr. ASTON: I went to assist Mr. Stearn in the summer of 1879, and was with him till the spring of 1880. All the lamps I saw at that time had horseshoe-shaped burners. I never saw any with straight burners. I have seen a good many lamps packed and sent off from Mr. Stearn's. I saw at least six packed in cotton wool about the month of August. The packing was going on all the time I was with Mr. Stearn, after testing. I had charge of the batteries which were in the cellar. There were about 30 cells. They were of the Bunsen type. The cells were afterwards increased to 60, and gave a better result. I could not fix the time or date of increase.

Mr. ROBERT ROBERTS, examined by Mr. FINLAY, said: I am a builder and joiner, and reside at Rock Ferry. In 1879 I was engaged on work for Mr. Stearn, at his house. That was during the months of July and August, 1879. While there I saw electric lamps. I have seen sometimes one, two, or three, or as many as half a dozen at a time. The burner was the shape of a long horseshoe, and appeared like a black thread.

Cross-examined by Mr. ASTON: I was frequently at Mr. Stearn's in the year 1880, and have often seen electric lamps tried by him. I never saw a burner that was a straight rod. All the burners I saw were of the loop shape. The lamps were lighted when I saw them.

Mr. PERCY SELLON re-called was examined by Mr. GRAHAM as follows: In the end of November last I went to the manufactory of Messrs. Carré, at 19, Rue de la Ville Estrapade, Paris, and I purchased similar carbons to those in the case now produced, which were about one foot long, and some of which were one millimetre diameter and others half a millimetre in diameter. These are some of the colours.

Mr. FINLAY: I want to exhibit F I B 2 to be identified by General Webber, one of the directors of the Anglo-American Company, who is not here at the moment; but, subject to your lordship allowing him to identify exhibit, we have completed the Defendants' case.

Mr. ASTON said his side desired to call evidence to rebut the evidence for the Defendants.

Mr. JUSTICE KAY: That you have a right to do. You have not called Edison.

Mr. ASTON: No, my lord.

Mr. JUSTICE KAY: Nor Cheesborough.

Mr. ASTON: No, my lord.

Mr. JUSTICE KAY: Then, do you object to the passage in Edison's subsequent specification beginning, "I have discovered," &c.?

Mr. ASTON: We leave that in your lordship's hands.

Mr. JUSTICE KAY: No, no, you cannot do that. It is for you to say whether you object or not.

Mr. ASTON: We cannot call Edison, my lord.

Mr. JUSTICE KAY: I do not wish to dictate to you for one minute. You do not call Edison, and you made an objection. All I want to know is whether you now object to this being received as evidence or not.

Mr. ASTON: Not as evidence, my lord.

Mr. JUSTICE KAY: Then you do not object. I cannot help using that against you for what it is worth if you do not object.

Mr. ASTON: Well, there it is, my lord, for what it is worth. We could call Cheesborough, but he is only a patent agent.

Mr. JUSTICE KAY: I do not wish to dictate to you as to how you are to conduct your case. Conduct it as you like; but I wish to know whether you object to this subsequent statement or not. I understand that you leave it for what it is worth.

Mr. ASTON: Yes, my lord.

Prof. JAMES DEWAR was then called on behalf of the plaintiffs, and examined by Mr. MOULTON: I am Professor of Chemistry in the University of Cambridge, and for many years have devoted my attention to chemistry and electricity. Since the year 1872 I have more or less continued my investigations on the behaviour of carbons both in the arc and by incandescent heating.

I take you to the specification of Edison's patent 4,576. You have been in court most of the time hearing the evidence of the witnesses for the defendants. I call your attention first to the evidence with regard to the process of carbonisation. In November, 1879, was the process of carbonisation a known process?—Yes, perfectly well known.

Had it been known for a long time?—Since the beginning of last century—1760 at any rate, and probably thousands of years ago.

Would you take this as a definition of carbonisation which has been given by Mr. Swinburne—"Carbonising is simply raising the proper material to a high temperature out of contact with air"?—Undoubtedly that is a very simple and fair definition.

It is almost identical with the definition of Prof. Thomson, taken from "Brand and Taylor's Chemistry." Is that a well-known book?—Certainly.

Were the steps necessary to be taken to perform this process of carbonisation well known in November, 1879?—Of course they were well known. Absolutely nothing has been added to the stock of public knowledge as to carbonisation, as regards carbonising filaments, as required for the objects of this specification, since November, 1879.

What were the precautions necessary to be taken as known in 1879?—Merely the exclusion of atmospheric air.

How was that effected?—That was effected by either heating in a close vessel, the volume of which was not very large in comparison to the size or body to be carbonised, or the substance was placed in a larger vessel, and packed in powdered charcoal or other inert substances.

Are these precautions sufficient to enable anybody to carbonise?—Perfectly sufficient; I have tried it hundreds of times.

Was the term carbonisation a chemical term?—Yes, it was a term perfectly recognised in technical science.

Mr. JUSTICE KAY: It was recognised when I was a boy.

Examination continued by Mr. MOULTON: Taking Cheesborough in 1871 I put to Prof. Silvanus Thompson his description of carbonisation. Was that common knowledge at the date of the specification?—It was.

In your opinion are the references to carbonisation in Mr. Edison's specification sufficient to direct a person wishing to perform the process there described, and to find out the precautions?—I think so.

It has been suggested that things so slight as filaments cannot be carbonised with sand. Have you tried the experiment yourself?—I have.

How did you try it?—I tried it with a crucible of about four cubic inches, the same size as that mentioned by Mr. Crookes. I then put in it sand, and about 100 pieces of vegetable fibre. Each length would be about four or five inches long, and the thickness before carbonisation would be about a fifth of an inch. Before carbonisation I put them close together in the crucible, then I filled it up with sand. The sand was coarse. I then luted on the cover in the ordinary way, and placed it in a crucible of larger size, knowing the material was very porous. The cover was placed upon the crucible and luted, and then I put the whole into a furnace. The furnace was at a full red heat at the time. I allowed it to remain there about two hours, keeping up the heat, and the result was as shown in the specimens I now hold in my hand (specimens produced).

Mr. JUSTICE KAY: Were any of those in the crucible destroyed?—I do not think so, but so far as I estimate, in the removal I lost about 3 or 4 per cent.

Am I to take it none were attacked by the oxygen in this process of carbonisation?—No.

Witness here produced three exhibits which were marked respectively I D 1, I D 2, and I D 3.

Mr. MOULTON: What kind of sand did you use?—It was common sea sand.

Will you explain the operations which in your opinion resulted in the process of carbonisation?—The sand physically displaced about two-thirds of the air. When carbonisation begins, wood or vegetable fibre gives off 250 times its volume of hydro-carbon and other vapours. At that temperature it would be 500 times its volume. This enormous quantity of gas of course displaces the whole of the air in the interstices of the sand.

After displacing the oxygen by the gases going off, would that have another effect in protecting the carbonising?—They would protect it because they are reducing the gases.

Was all this known in 1879?—Yes, perfectly well known.

Mr. JUSTICE KAY: As this has already been made entirely clear by witnesses on the other side, we need not go over it again.

Examination resumed: Any person in 1879 wishing to carbonise a small body like a filament, do you think he would have any difficulty in doing so?—No difficulty in the world.

In the instance given you put the crucible into a larger crucible. Have you also performed the operation without the larger crucible?—I have performed the same operation by using a plumbago crucible.

They are thicker in the walls?—Yes.

Mr. JUSTICE KAY: Would that have some effect on the carbon?—It may; but it is chiefly want of porosity and thickness of the walls that prevail. It was packed in the same way, and the experiment was perfectly successful; just as much so as the other.

Have you mounted any filaments carbonised by yourself?—Yes, I have mounted one of these filaments in Edison's way, and exhausted it. The lamp is not very elegant, but it is perfectly practicable. [Lamp produced, marked I D 5.]

What do you mean by Edison's way?—By fixing the filament on to the platinum by carbonisation with the lampblack wires and then carbonising it.

In the carbonising of that lamp did you use anything that was not common knowledge in 1879?—I did not.

Mr. JUSTICE KAY: How long did you run it?—I ran it for several hours.

In your opinion does that lamp show any signs at all as yet of breaking down?—I do not think so. The darkness of it is partly due to the manipulation of the glass being bad.

Examination continued by Mr. MOULTON: For the purpose of a useful filament being made, in your opinion is it necessary to take any precautions against distortion?—None other than the packing which I have described, either in fine sand or in fine charcoal.

Have you tried to make a lamp in any of the ways mentioned in Edison's specification?—I have tried making an experimental lamp with a tar putty filament.

First, with regard to rolling it out, what is your opinion on the point?—It is merely a question of manipulative skill.

How do you roll yours out?—I simply roll it out on two flat surfaces.

What were your surfaces?—I took two surfaces of brass, but it does the same on a flat surface of paper or wood so long as it is flat.

Do you think it was necessary, in order to enable a person to roll this out, that any special directions should be given?—I do not think any directions would enable one to roll them out if they had not manual dexterity.

With regard to operations in which tar and lampblack are to be combined, what do you say?—I say Edison's description of the consistency of the material to be employed is the only mode in which you could convey a physical state to this body which will work.

Do you think any person trying to perform the process described in the specification would have any difficulty with carbon filaments?—I do not think so.

With regard to the length of the filaments, what do you say?—I say there is no difficulty in rolling the filaments to different lengths.

And, do you think it was necessary or requisite to mention any special length?—I do not.

Digitized by Google

Witness here produced an experimental lamp which he had made from lampblack. The exhibit was marked I D 5.

Will you tell his lordship how you made that lamp?—This is simply a lampblack tar putty filament which I rolled when carbonised, and attached it with the lampblack to the wire. I carbonised the putty and tar putty at the same time with the two platinum wires inserted.

Mr. JUSTICE KAY: Was this done in sand?—No, it was done in carbon.

By Mr. MOULTON: With the platinum wires attached?—Yes. Afterwards the two platinum wires were slipped into the other two, heated through the glass without clips.

Have you run that lamp?—I have.

With what result?—I think it is a very good experimental lamp indeed.

Supposing that mode of constructing a lamp were reduced to practice and used on a large scale, in your opinion would it turn out a practical and useful lamp?—I see no reason whatever why it should not.

Can you tell how long it would last?—I cannot, but I have run it for about two hours.

This lamp was neither run on the pump nor subjected to Cheesborough's process?—No.

Would these processes have improved it if they had been used?—Yes, immensely.

I would next ask you as to your other experiments?—I cut from a length of platinum wire two equal pieces. I placed one of the pieces in fine lampblack and heated it to a white heat in a furnace for about two hours. I then took the resulting platinum. It has the appearance of being slightly attacked on the surface. In order to test its porosity I sealed it into a vacuum tube. Then I had a similar tube, into which I sealed the platinum wires which had not been carbonised. I exhausted the two tubes simultaneously, so that they had each the same vacuum. They were connected. They were then of identical appearance when the electric discharge passed. I sealed the connecting tube so as to secure the connection. I then passed the electric discharge. The appearance was exactly the same. I measured the appearance by the striation. If there was the slightest leak into one of these tubes, the alteration in the appearance is the most delicate test we have of an impaired vacuum. I repeated that operation after standing twenty-four hours, and the tubes remained of identically the same appearance.

Take now W C 22.—There are two separate pieces of platinum wire, which were placed in the same crucible, the only difference being that the spiral P 2 had lampblack containing a little sand mixed with it. The crucible was subjected to a white heat for more than in hour. The result shows the deleterious effect of silicious compounds in presence of carbon and platinum.

Did you examine scientific periodicals on the point to see if this phenomenon had been observed by other people?—It is quite well known.

I do not know whether you yourself have tried the method of making a lamp by rubbing tar putty on thread?—Merely experimentally; I never mounted any such.

Did you find any difficulty in carbonising?—None whatever.

Examination continued: I have myself rolled filaments of lampblack and tar. If rolled fine the filaments can be made into the form of a spiral. I have a specimen of a filament so coiled. Supposing the winding of the spiral was made so close as in that specimen, it would have the effect with regard to radiation which Edison mentions. Judging from my experiments, all the methods of making filaments mentioned by Edison can be carried out. I have tried the coiling round a helix of copper wire and succeeded in carbonising. I heated it with diluted nitric acid to dissolve away the copper. I did not mount that filament, but was satisfied it was a practicable thing. Nitric acid has no action on carbon.

The Court then adjourned for luncheon.

After luncheon the examination of Prof. DEWAR was resumed by Mr. MOULTON, as follows: I ran one of the lamps which have been put in for about 20 hours. It was at white heat. It gave a good light. Beyond the fact that the glass was not so clear I have not the slightest doubt that it would work well if properly exhausted. With regard to the non-conducting non-carbonisable substance mentioned in Edison, I gather that its intended use is to isolate one coil of this close spiral from touching the other during carbonisation. I have tried experiments with the coating upon a filament to see if the lamp would be a workable one. The specimen I produce now is an ordinary Edison lamp, the filament of which is made, I believe, of bamboo fibre, which I opened, and coated the filament with lime. I thereafter exhausted the bulb, and ran the lamp for about three hours. A great portion of the lime has been knocked off by the action of the current. I think it is due to the high velocity of the residual particles of air always left in the bulb. I say that used in Edison's way—an exceedingly thin coating on the outer surface—does no damage to the working of the lamp.

It has been said that filaments must be freed from impurities in order to give them proper life. Is that necessary?—I say it is not.

Examination continued: Parchmentising to a certain extent takes out the impurities. The parchmentising process is not intended to deal with impurities, but with the character and structure of the resulting carbon. With that exception it does not alter the construction, but it makes the carbon more homogeneous. It is a matter of practice to get lamps that offer the same resistance and run together. With the exception of Cheesborough's process, I do not know of any way that would make the lamps uniform. Before the date of Cheesborough's specification I made a great many experiments with carbon, especially in connection with the electric arc. I have known Deprez's Paper since the year 1872, and before that; I know the kind of carbon deposited by that process. In 1879 I was engaged in a research which made me very anxious to get carbon tubes which were not porous. I tried to improve all the carbons I could find in the market by subjecting them to Sidot's process. I did not, however, succeed. It never struck me for one moment to employ Deprez's process to improve carbon and make it non-porous. The effect of Cheesborough's process is exactly what he has described; it produces a carbon which is much more homogeneous than can be produced by furnace deposition. The hydro-carbon forms a deposit which lodges in the carbon. Flashing renders the filament much more stable, more elastic, less liable to disintegration of the lamp, and of course thereby increases the light of the lamp, enabling it to be run at a higher temperature and for a longer time. It has been proved that this deposit of carbon gives a greater proportion of light say for the same expenditure of energy. With regard to the process as described by Cheesborough, it is an admirable description. Supposing the second process there described be used, the carbon pencils would be suitable to light incandescent lamps. I say there is also a fair description of the substances, all of which work satisfactorily in the way. Referring to Deprez's Paper, there is nothing in it that led me to use the Cheesborough process. I do not think Deprez's was well known, unless to specialists working in carbons at high temperatures. I cannot say from reading Deprez's Paper whether the experiment with the carburetted hydrogen was incandescent or arc. I made a lot of experiments in 1866, before the last action. I have some of the specimens of Sidot's process which I made for the last trial. I have repeated the experiment which was described by Mr. Crookes, and I find the reduction of the calcium only takes place when the arc temperature is reached.

The Court adjourned at four o'clock, to meet next day (Tuesday), at half-past ten o'clock.

TUESDAY, MAY 14TH.

The examination in chief of Prof. DEWAR was continued by Mr. MOULTON as follows:

Have you brought specimens of the wooden fibre you used?—Yes. [Specimens produced.]

Uncarbonised?—Yes.

Have you brought the glass with which you rolled the filaments?—I have.

Witness here produced the two plates of glass with which he rolled the filaments. Thereafter he rolled a filament about one-fiftieth of an inch thick, and handed the same to his lordship, by whom it was inspected and handed in turn to the learned counsel. Witness subsequently attached the platinum wires and exhibited the finished article as before.

Mr. MOULTON: What amount of mineral impurity has such a thing as lampblack and tar?—Well, it varies very much.

Would it have more or less than vegetable fibre?—About the same.

The specimens made by witness were then put in, and marked I D 14.

Mr. JUSTICE KAY: Do I understand you prepared that putty yourself?—I did.

By Mr. MOULTON: With regard to the platinum, in your opinion is carbide of platinum formed in the process of carbonisation?—I have never been able to find carbide of platinum formed by igniting carbon of a high heat in presence of lampblack.

Have you tried the experiment of coating filaments with lime and running two lamps, one coated and the other not coated?—I have. [Shown two lamps.] These are two of Edison's lamps made of bamboo filament, one of which I opened last night and coated the filament with magnesia. I ran the two lamps at the same time thereafter for an hour. There is a deposit in one of them. There is a difference in luminosity; the radiation from the magnesia differs from the radiation from the carbon; it looks more luminous in some parts, but generally it looks darker relatively to the carbon. That optical effect depends upon the thickness of the coating. I ran the lamps about an hour. [Lamps put in and marked.] The blackness is probably due to opening the lamp. The filament is severely tortured in putting the coating on. I have had occasion to observe the behaviour of lime in presence of carbon. In conjunction with my colleague I made experiments at the highest temperature we could produce in a furnace, and at that temperature we could get no evidence of the production of calcium by the action of carbon on lime.

Cross-examined by Sir HORACE DAVEY: You told us yesterday of the chemical action of carbonisation which was older than the time of Du Bois Reymond, and you took us back to the middle of last century; what I want to direct your attention to is this question: Prior to 1880 for what purpose was carbon used, in what trades or manufactures?—It was used, of course, for gunpowder, for every process in which carbon was wanted in combustion; it was employed in every chemical laboratory.

I am asking you in what trades or manufactures was the process of carbonisation employed?—Do you mean wood carbons?

I am saying what I mean, the process of carbonisation; in what trades or manufactures was the process of carbonisation used?—I say it was used for gunpowder making, it was used for the production of charcoal, it was used in every chemical laboratory, and especially in connection with blow-pipe works.

For the purposes you have described, was it or was it not necessary to provide against the deterioration of the carbon—I must not say destruction, I believe, but the deterioration or consumption of the carbon—in making these small carbon filaments?—I say no, it is still carbonisation whether a big substance or a small one.

Was it so important in carbonising for the purpose of gunpowder manufacture and the other manufactures you have mentioned to exclude the oxygen as it is in making these small filaments?—I think so, if you wanted a good result.

Then you do not agree with the gentlemen who have already given evidence?—I say no one would carbonise in presence of air.

Mr. JUSTICE KAY: Do you know any trade or manufacture in which ordinary workmen are employed in which the same precautions are taken as are now taken?—I do not know of any manufacture previous to that unless the use of gunpowder for blow-pipe purposes.

Digitized by Google

Mr. JUSTICE KAY: The effect of your evidence on my mind is this. Except in chemical laboratories, and by people who have a knowledge of chemistry, no such precautions were taken in any ordinary trade or manufacture?—I do not think there was any use for them except for blow-pipe work, or work of that kind.

I think you told us yesterday that in your opinion nothing had been added to the special knowledge with regard to the carbonisation of these filaments since the November of 1875?—I said the abstract principle of carbonisation remained the same.

The abstract principle. I understood you to mean the method of carbonisation?—I am using the word method as to heating in a close chamber or heating in a large vessel.

Have you directed your attention to Edison's specimens and the patent dated 15th December, 1879, entitled the "carbon patent," and, if so, did that add anything to the existing state of knowledge on the subject?—No, that patent is simply a patent of detail.

I am aware of that; but I am asking you if this method of carbonisation added anything to the existing state of knowledge?—I say nothing to the method.

Edison did not think that, did he?—No; he did not.

I will refer you to the claim. Did not Edison conceive himself, rightly or wrongly, to have taken precautions against distortion in carbonisation?—I have no doubt he found it an advantage of detail to use a mould; but I say that added nothing to the knowledge of the method of carbonisation.

I am afraid we are using method in a different sense. I mean carbonisation as a process for the purpose of making carbon conductors for lamps?—Probably he found that this was an advantage; but that did not prevent another method from giving perfectly satisfactory results.

I will refer you to Edison's next patent, which is what we call the bamboo patent, and is so long that none of us have been able to read it. Having quoted from page 50, book 3, Sir HORACE DAVEY asked: Would a lampblack and tar carbon be a carbon that is purely structural?—I think he uses the word structural there as a word relating to vegetable fibre.

Would a carbon formed by carbonising tar and lampblack be expressly structural in the sense in which Edison uses the word there?—I think not. I take it he means vegetable fibre.

Passing on to page 54, line 7, was it known before that date that in carbonising those small things there was danger of rupture or distortion?—I say yes. It was well known in the case of the carbonisation of wood that there must be a large amount of contraction—20 per cent. of the original wood.

Was there any necessity prior to this time for taking measures for the purpose of preventing that distortion, and to provide for the contraction that takes place?—I say in the case of packing filaments in wood, charcoal, or lampblack, that forms a mode itself which allows for contraction. But the mere fact that a filament is distorted does not prevent its being used in a lamp. They do not look quite so well, that is all.

Can you refer me to any prior publication of any sort or kind in England in which measures had been indicated for the purposes of preventing the inconvenient results which Edison here points out?—I do not think there was any demand for it. Do you include any scientific Paper?

Yes, I will take a scientific Paper.—I say it was well known in the year 1868. It was published in the *Philosophical Magazine* in 1868, and there were then set forth details on the relative contraction of wooden fibre in carbonisation and the production of tubes of small filaments complete. That Paper was by Dr. Gore, of Birmingham. There the carbonisation was done simply in a glass vessel.

Then in your opinion did this passage to which I have referred, and the means pointed out by Edison to get over these difficulties, add nothing to the stock of knowledge at that date?—I say they added to the improvement of the manufacture, that is all.

Then do you dispute the statement "During the process of carbonisation there is sometimes danger," or do you say that that was well known?—I say so most decidedly.

You told us in your experiments you packed your crucible in sand and put it in another crucible?—I did.

What proportion in bulk before carbonisation did the filaments bear to the whole contents of the crucible?—A very large ratio. The vessel had 40 times the volume of the filaments, which I consider enormous.

The rest was sand?—Yes.

Referring to the experiments of Mr. Crookes as to packing filaments in dry sand, so far as the details of the experiment spoken of by Mr. Crookes are concerned, you have no objection to make?—So far as they are recorded here, all I say is, I made similar experiments. His were burned out, mine were not.

Some of yours were?—Not that I am aware of.

Did you mix any carbonate of lime in it?—Absolutely nothing.

I think you say you produced lamp I D 5—the lamp made of this putty wire. Do you call that a filament?—I do. It was the best one I could make at that time.

What is the diameter?—I should think it is half a millimetre, about the 30th part of an inch.

I would ask you again whether you call it a filament?—I do not say it is a filament as I understand Edison's specification, because it is not so fine as he intended to roll them.

What do you understand by a filament?—A very fine thread.

I think you told us you tried that lamp, running it for a certain time. There is some distillation of the tar?—There is some slight distillation.

Would that distillation of tar inside the lamp produce gases of some kind?—If the temperature was high it might.

Would not the presence of tar in any form in the lamp *pro tanto* be a disadvantage?—Undoubtedly; I do not think anyone in repeating the manufacture of a lamp would allow tar to appear again.

You told us coating would not do any harm in a lamp. Would it do any good?—That I am not prepared to say.

Do you see the slightest utility from it?—Yes, I think I do. Lane-Fox first suggested coating with these bodies, or, at least, simultaneously with Edison, from an excellent idea, viz., of endeavouring to get more light for the same expenditure of energy; but whether or not that is the result I cannot say.

The cross-examination of this witness had not concluded at half-past one o'clock.

Mr. ASTON, for the purpose of interpreting the word "moistened," as used in the case, quoted from the book of Job, "His bones were moistened with marrow."

The Court then rose.

WEDNESDAY, MAY 16TH.

The cross-examination of Prof. DEWAR was resumed by Sir HORACE DAVEY, as follows:—

Have you made any calculation, on the basis you told me, of the electrical energy employed by Deprez, assuming he used 600 Bunsen batteries arranged in the most favourable manner?—Yes, and the result of my calculation is that it was from 30 to 100 amperes.

In making that calculation what did you assume to be the electromotive force of each cell?—I took it roughly as two volts.

And the internal resistance of each cell?—Less than one-tenth of an ohm.

What size did you assume the cell to be?—I took the largest cell which we used in the laboratory at that time—pint size.

Do you say it would be only about one-tenth of an ohm?—Yes.

As to Cheesborough's patent and impossible substances non-conductors of electricity, what have you to say of the list of Mr. Crookes?—I think the reference is to bodies which would be impossible under the conditions of Cheesborough's experiment. These are bodies which you may say are not easily fusible, but they are, many of them, easily fusible under the conditions of Cheesborough's experiment.

Apart from Cheesborough's experiment, are not those bodies such as you would, as a man of science, describe as infusible substances, non-conductors of electricity?—I should not. I say a great many of the silicates would fuse at the highest temperature.

Did you require much practice in rolling out the lampblack and tar filaments successfully?—I required no practice.

You succeeded the first time you tried?—Yes.

Re-examined by Mr. ASTON, the witness said he had made many experiments in 1886 with the Cheesborough process, but never at the time tried coating non-conducting substances with carbon and treating them in Cheesborough's way. Since the suggestion had been made, however, he had tried it, had mounted the burner in a lamp, and had run the lamp for some time. A prior publication of the means of preventing the inconveniences indicated by Edison was to be found in a paper in the *Philosophical Magazine* for 1868, on "Details in Relative Contraction of Woody Fibre in Carbonisation, and the Production of Tubes in Small Filaments," by Dr. Gore. This Paper contained the same things as Edison described. Distortion of filaments in carbonisation did not affect their efficiency necessarily; the appearance only would be objectionable. Distortion, short of rupture or of short-circuit in the spiral form, would do no harm. Rubbing fine clay into the putty, as done by Mr. Crookes, would not, in his opinion, be a proper mode of coating a filament. He had carbonised filaments in a closed crucible with and without putty. There was no difficulty in manipulating lampblack, and the filaments by carbonising in a closed chamber without packing; that was, in fact, the best way to carbonise these filaments.

A small crucible was produced, handed to the witness, who said: In that crucible I have, with Mr. Gimingham, carbonised filaments in the precincts of the court, using no packing and no luting of any description. The filament was a thread, so far as he could remember.

Sir HORACE DAVEY urged that this did not arise out of the cross-examination.

Mr. JUSTICE KAY said it should have been produced in the examination in chief. If it were pursued Sir Horace Davey would be entitled to ask any questions upon it.

Sir HORACE DAVEY, cross-examining: About what heat was this produced at?—It was a mere experiment. It was a spirit lamp that was used.

Do you suggest that this coil, or whatever you like to call it, has been heated to a sufficient heat for use as a conductor in an incandescent lamp?—Not at the present time.

Then it is not completely carbonised?—It is carbonised; but it does not conduct well enough. It wants to be heated for a longer time at a higher temperature.

Has it been heated to a degree at which the oxygen would combine with or attack the carbon?—That I cannot say. I think it is probably at a low red heat.

Mr. JUSTICE KAY: I am very much disgusted. I am here trying all I can to understand the case, and this is clearly an attempt to mislead. I am greatly disgusted.

Prof. DEWAR: I have no desire to mislead your lordship. I have stated that this was a mere experiment. I did not produce it. It was put to me.

Mr. JUSTICE KAY: You may stand down.

Dr. JOHN HOPKINSON, re-examined by Mr. MOULTON, deposed:—I have heard the evidence given on behalf of the defendants in this case, and have made experiments on various points arising out of the evidence. I have seen experiments made with regard to the possibility of carbonising a tar and putty filament in a close chamber without any packing at all. The filaments were carbonised and subsequently

Digitized by Google

mounted into lamps and tested. I have seen the same thing done with linen and cotton thread carbonised in like manner without any packing. In that case I should say the platinum wires passed through a glass mounting. The platinum wires had been attached before mounting. There was only one filament in the tube, it was thoroughly well carbonised, mounted in a lamp and the lamp exhausted. In the former case of the putty filament it was wrapped upon a cylindrical rod of wood before carbonising, after the attachment of the platinum wire. That rod had to be supported in the cylindrical chamber. From the results of these experiments there is no doubt carbonisation can be successfully performed in a closed chamber without packing. The temperature was kept at full heat about half an hour, at first the blow pipe was put on rather lightly, and afterwards increased. With regard to the process of carbonisation, the heat need not be as high as that at which carbon would unite with oxygen.

Mr. JUSTICE KAY: What heat would this be, compared with furnace temperature at which filaments are now carbonised?—It would be below furnace temperature.

Would it be higher or lower than the heat at which filaments are now carbonised?—I should think below.

How much lower?—I cannot say. I can only define it by saying the temperature was just over that which would melt brass.

In one case the substance was tar and putty, in the other thread, and there was a little bamboo as well. There is no doubt the filaments were perfectly carbonised; they were put in lamps, which lamps, so far as I could judge, were perfectly good. We measured all the lamps. [Shown lamp.] That is the lamp with the lampblack and tar and the very fine thread rolled into it. It was carbonised in the way I have described. [Shown another lamp.] This was made from a cotton thread carbonised in the longer cylinder, attached first of all by tar putty platinum wire. It was carbonised in a tube without any packing in the way described. That was measured at 6½ candles, and it then took 67 volts ·85 amperes, which also works out to little less than 8 watts per candle-power. [Shown thread.] This is just like the thread that was used to roll in the tar putty for I H 6. [Thread marked I H 8.] I have seen carbonisation in sand. [Shown box.] That box contains the materials that were used—the crucible and platinum cover, also some of the sand, and one or two bits of broken filament. There were pieces of cotton thread, paper, and bamboo put into that. They were heated in the gas furnace to a bright furnace heat for about a couple of hours. They were then taken out, and in this box are some samples of the filaments which resulted.

Witness was further examined as to other lamps similarly produced. Continuing, he said: I have seen experiments made to see whether a lime cylinder subjected to Cheesborough's process can be raised to incandescence. I have satisfied myself on the point. We tried the experiment twice; the first time we failed, in the second we succeeded. The cause of failure in the first case was that the means of controlling the current were insufficient, consisting of plunging a metallic substance into a greater or less depth of a liquid, and so leading the resistance. The result was that the current suddenly sprang up to an exceedingly high degree of intensity. We repeated the experiment with better means of control, and succeeded. A little rod of carbon was thrust through a cylinder of lime. The ends of the carbon were supported by larger pieces of carbon, and the lime stood between the two pieces of carbon. It was then placed under a receiver, and coal gas was introduced in place of the air. It was then heated by the passage of the current, carbon was deposited, and here is the result. [Specimen produced.] The lamp now exhibited, if filled with nitrogen, would be very similar to Fig. 1 of Cheesborough's specification. The differences would have nothing to do with the behaviour of the conductors.

Mr. JUSTICE KAY: What am I to gather from this? I do not understand the object of these questions. This is only a carbon treated according to Cheesborough's process.

By Mr. MOULTON: Did that compound conductor stand incandescence?—Yes, it was heated for the better half of half an hour to a bright yellow, while the deposit was going on, but no further gas had been admitted during the latter portion of the time.

Are you by that experiment able to say oxygen will reduce the lime at such a temperature?—I see no signs of reduction there.

Assuming it was desired, would a conductor so made in an incandescent lamp stand?—I see no reason to doubt it.

Examination continued, and witness asked as to the instructions in Edison's patent for the making of lampblack and tar filaments, he said the instructions given to make the substance of the consistency of thick putty were the best that could possibly be given. He did not see that the instructions as regards rolling would prevent success. The filaments in the lamps put in were rolled in his presence between brass plates. The finest he had seen was about a hundredth of an inch, sufficiently fine to make practicable lamps of high resistance. At the date of the patent the knowledge of the present day with regard to carbonisation was in existence. The method of making the connection with lampblack and tar was perfectly practicable. He had seen many tar-putty joints successfully made. An experiment was tried in his presence as to heating lampblack in contact with platinum. The description given by Prof. Dewar was complete. The platinum wires in the upper part of the crucible in lampblack alone were to his eye uninjured, whilst those in lampblack and sand had become very brittle. As to the filament with the non-conducting non-carbonisable substance, he agreed with Prof. Dewar regarding it.

In your opinion are the directions as given in Edison's specification for making a lamp, sufficient to enable one willing to make the process succeed to make a practical lamp?—Yes.

And, in your opinion, would the various methods there described succeed in making a practical lamp?—I think so. I have seen a large number of them.

Now, with regard to the Cheesborough. Are the directions in Cheesborough sufficient to enable any practical person wishing to perform the process to do so successfully?—Yes. I think they are all really very explicit.

In your opinion, is the effect of Cheesborough's process to improve the carbon of an incandescent lamp?—I think there is no doubt whatever of that; it does improve it.

As to efficiency and duration?—Yes; I think almost everybody uses it.

The Court then adjourned for luncheon. On the Court resuming,

Dr. HOPKINSON was cross-examined by Sir HORACE DAVEY as follows:—

Do you seriously suggest to the Court that any workman in the year 1879, or any other time, if he wanted to carbonise a material, would use one of these brass tubes and a blow-pipe?—I think it is very likely.

As a commercial way of carbonising?—Whether it would do or not commercially I do not know.

I am speaking of a man engaged in the manufacture of lamps from carbons to be used, and I am asking, do you seriously suggest to my lord that such a man would use a brass tube and a blow-pipe?—I think if he were making one filament it would be the most natural thing he could do; if he were making a great many, he would probably introduce some material into the chamber.

Would any man in his senses do that?—I would not put it so strong as that; but he might adopt a more economical way of doing it.

You put that forward as what Edison tells you to do?—Yes.

Where do you find anything about a blow-pipe?—I find nothing about a blow-pipe, I only find a high temperature.

Did you put your brass tubes into the furnace?—No; I would not like to melt the tubes.

Before the bulb was closed you passed the electric current through the conductor so as to let it run the lamps?—No; I think in the case of those that were flashed that might be said to be done.

I am talking about running on the pumps?—No; I did not.

You put the platinum wires into these brass tubes?—Yes.

With a piece of glass between them?—No; the only cases in which glass was used were in one or two of those experiments where the platinum wires were through the glass.

You put the glass and all into the brass tube, closed the tube and exposed it to the heat?—Yes.

Was the glass melted?—No.

What is the melting point of glass?—It varies considerably according to the composition of the glass.

But is it considerably below red heat?—No; glass becomes softer and softer till it is quite soft. For thoroughly melting glass you require a bright white heat.

Does it take to become soft considerably below red heat?—It begins softening somewhere about red heat; but that, again, depends upon the quality of the glass.

In your experiments you used sand, I observe, very fine white sand?—Yes, it is the white sand they use for making the first quality of glass.

Is not that sand pure silica?—Yes.

And does it not contain any water or moisture?—That depends on circumstances. It is generally washed and dried. Generally it contains a good deal of moisture.

As compared with other sands, would that fine sand contain a very much larger amount of moisture or water?—I do not think so.

Will you show me, from one end to the other, one single line in Edison's specification which tells you you are to get rid of all the tar?—He calls your attention to that specially, so far as I remember.

In reply to further questions, witness said distortion *qua* distortion is harmless; it is only a matter of appearance.

Prof. FLEMING, examined by Mr. ASTON, said: I remember in 1879 a Mr Johnston, assistant to Mr. Edison, coming over to England. In 1880 he brought with him a box containing some half-dozen carbon incandescent lamps. He left those lamps in my charge. At that time I was acting as the scientific adviser of the Telephone Company, whose offices were at 11, Queen Victoria-street. Mr. Johnston requested me to make arrangements to run these lamps. They were put up in a room and operated on by galvanic batteries. They were arranged in parallel. I examined the lamps, and I can state they were carbon incandescent lamps, with bulbs made entirely of glass, and platinum wires sealed therein. The platinum wires, so far as I can recollect, were united to the carbon with little clamps. The carbon conductor, to the best of my recollection, was a very thin strip of paper in a horseshoe shape. I was told the glass bulb was exhausted. [Shown lamp.] To the best of my recollection this lamp is very similar to those exhibited in Queen Victoria-street in the beginning of 1880.

Sir HORACE DAVEY said that was the worst form of a leading question.

Mr. ASTON: I am only sinning in the same direction as my learned friends.

Mr. JUSTICE KAY: No man excuses himself by another man's errors.

Examination continued: I had no doubt the lamps I tried were good efficient Edison lamps. They gave an excellent light. They were exhibited on and off for several weeks from time to time. Sometimes they were run for some hours; the current was turned off, the battery renewed, and the current turned on again. Since that period I have been familiar with the manufacture and working of incandescent lamps. Those were efficient lamps that Edison sent to me through Johnston. A number of persons were brought to the rooms from time to time to see the lamps. There was no secrecy about them at all. The two gentlemen who arranged the batteries saw them regularly. I have witnessed experiments upon carbonising filaments in a close chamber. They were the experiments which Dr. Hopkinson has referred to. The filaments were made, as described by Dr. Hopkinson, in the brass tubes, at a temperature given by a blow-pipe

Digitized by Google

flame, at a heat a little below the melting point of brass. The heat carbonised the filaments very thoroughly. I agree with the evidence of Dr. Hopkinson as to carbonising these filaments. If put on the pump and flashed, they would be quite equal to filaments in ordinary use. I co-operated with Dr. Hopkinson in taking the electrical measurement of those lamps, and on that point I agree with him. With reference to carbonisation in sand, the sand taken was a fair sample of ordinary silver sand.

Mr. JUSTICE KAY: Have you tried the experiment of carbonising a filament in damp sand?—No.

Do you think anybody would use damp sand?—I should think it improbable that anybody would use damp sand.

Examination continued: Prior to 1879 I was familiar with the literature on carbonising. I cannot say positively whether before 1879 I knew about carbonising with charcoal.

Mr. JUSTICE KAY: When did you first learn that?—Several years ago, but not before 1879.

Was it 1880 or 1881?—I should think it would be somewhere about 1881 or 1882.

By Mr. ASTON: Previous to 1882 I had no experience of carbonising filaments. I have seen the process of rolling out lampblack and tar filaments by Prof. Dewar. I have tried the same thing and succeeded very well indeed. I rolled out one to the diameter of about $\frac{1}{1500}$th of an inch. The material was a mixture of lampblack and coal tar which Mr. Gimingham gave me. The material was of the consistency of thick putty. The operation of rolling requires nothing but a little manual dexterity. The filament I rolled is one of the exhibits. W C 20 is the filament made from the tar putty which Mr. Gimingham gave me, and is rolled out to the $\frac{1}{1500}$th of an inch. None of the filaments I rolled were put into lamps. I saw filaments rolled by Mr. Gimingham put into those lamps of which Dr. Hopkinson has spoken. It is marked I H 6. It is a good serviceable lamp; it has a fine thread rolled in it.

Did you see any filament rolled in your presence and afterwards put into a lamp that had no thread in it?—No; I do not recollect having seen a filament without any thread, and afterwards put into a lamp.

Have you seen a filament made and introduced into a lamp in which camphor was used?—I measured such a lamp with Dr. Hopkinson.

Examination continued: It was run for about ten minutes; the result was 53 volts 2 amperes and 27 ohms hot. We had no record of candle-power. The lamp was run to a bright white incandescence. During the time we saw it run it was an efficient lamp. There was a little tarry matter at the top of the bulb from the joint. That occurred in five minutes. That discoloration is caused by a little tar driven out from the clamps when the lamp is run. The clamp is made by putting over the carbon and platinum wire tar putty paste. It was from that that the discoloration was evolved. It was evolved almost as soon as the running began. The discoloration does not impair the efficiency of the lamp, because it does not appear round the illuminating part, but only round the face.

Shown lamp produced by Dr. Hopkinson, in which the platinum filament was attached to carbonisation, witness was asked—

Are those platinum wires injured so as to destroy the efficiency of the lamp?—Not in the slightest.

Shown another lamp, and asked, What do you think about that?—I recognise this as one of the Edison lamps made in America, and delivered over in this country within the last few months. This lamp I know from the examination of precisely similar lamps, but with the same bulb and by the bamboo filament, and I know that by microscopic examination. The filament is attached to the leading wires by plastic carbonisable material.

Examination continued: As to impurities, if an impurity is uniformly distributed through a filament, and does not exceed a certain amount, it does no harm. An ordinary cotton thread will do for a filament. We do not use at the present time ordinary cotton thread, but cotton thread which is parchmentised. I have made a filament of cotton thread without being parchmentised, and have tried it in a lamp. The lamp is marked I H 7. The thread has not been purified in any way. Woody fibres might be used without being purified. One of the lamps put in this morning was so made. It is I H 1, and made from bamboo filament.

Cross-examined by Mr. FINLAY: You said you do not now use cotton thread unparchmentised; did you ever see a lamp made of cotton thread unparchmentised before I H 7?—Yes.

When?—Two years ago.

For what purpose was that lamp made?—A good many of these lamps were made for the purpose of the Woodhouse and Rawson action.

May I take it that so far as your knowledge extends there never has been a lamp made with cotton thread unparchmentised, except those made for the purposes of litigation?—Not so far as I know.

Take I H 10; has that got 10½ watts per candle-power?—Very nearly that.

Is not that an enormous expenditure of energy?—It is enormous as compared with some, very small as compared with others.

Three or four is about the usual thing, is it not?—Three or four is, I think, given for lamps that have had all the modern improvements applied to them.

When did Mr. Johnston bring the lamps to this country?—Mr. Johnston brought over the lamps in February of 1880.

Are you familiar with the specification taken out by Mr. Edison in 1879 for making filaments out of carbon?—I am, generally speaking.

Have you any doubt that these lamps brought over in 1880 had been made in accordance with Edison's specification?—I do not know in accordance with what specification they were made.

Did they look as if they had been made according to the directions of that specification?—I cannot say.

Were the clamps such as are described in that specification?—I cannot recollect the exact details of the clamps.

Look at the figure in book 3, page 37; were not the lamps exactly like that figure?—I cannot say they were exactly like it; they were similar.

Was there any point in which you can suggest they differed?—I do not think the bottom part of the lamp was finished in the way this is.

Am I to take it that they were generally the same as this drawing?—They were not very dissimilar.

With regard to the experiments with the brass tubes, have you ever known filaments prepared for commercial purposes by such means?—No; I do not know that I have ever seen filaments prepared for commercial purposes in brass tubes.

Is it not utterly unsuitable for the purpose of commercial manufacture?—It is not, perhaps, the best arrangement that could be devised for manufacturing them on a large scale.

Mr. JUSTICE KAY: Do try and answer like a witness, not an advocate. You know what the question is.

Witness: It is not the way that would be adopted on a commercial scale.

Mr. JUSTICE KAY: Would it not be much too costly to use it for commercial purposes?—It would be much too costly.

By Mr. FINLAY: Was the sand you used free from clay?—I did say it was pure sand.

By that you mean it was free from clay?—I did not analyse it.

Have you ever tried a lamp made with tar-putty filament for duration?—I have seen lamps tried that were made with tar putty.

By whom and when?—They were made by Mr. Edward Gimingham two years ago.

For the Woodhouse and Rawson litigation?—Yes.

Was any evidence given with respect to these in that case?—I think not.

Do you recollect what the results of the experiments were?—So far as I recollect the lamps were very satisfactory.

Do you represent that a lamp which darkened in that way in five minutes would be a good commercial lamp?—Yes, I say it would.

Blackening is produced by decomposition of the tar?—By the tar driven out of the clamps.

Have you any doubt that the decomposition of the tar when the lamp is running would impair the vacuum?—No, I do not think it would.

Re-examined by the ATTORNEY-GENERAL: I was a witness at the last trial. The defendants were Woodhouse and Rawson. They are still manufacturers of lamps. I recollect no such suggestion as that a competent workman could not make a lamp from this specification of Edison's. I could lay my hands on plenty of lamps in London which are now running at not less than ten watts per candle-power.

Dr. HOPKINSON re-called, examined by the ATTORNEY-GENERAL, and shown lamps: I received these lamps on or about 23rd March, 1880, from Mr. Waugh. They were sent to me by Mr. Edison. One has a filament broken and the other unbroken. In the unbroken one the vessel is entirely of glass; the leading wires pass through it, and I have no doubt there is a vacuum. The conductor is a carbon, and I believe is made from paper. The other one is identical, though the filament happens to be broken. I measured the resistance of the lamp; it is 170 ohms. So far as modern improvements are concerned, probably it would not be as good as a modern lamp.

Cross-examined by Sir HORACE DAVEY: It is very like the lamp Dr. Fleming described as having been sent to him. The joints are made by mechanical clamping, similar to what Mr. Finlay read from Edison's subsequent specification to Dr. Fleming. The filaments, I have no doubt, are made from paper.

Can you tell me whether or not prepared in the manner we describe as the cardboard pattern?—No; I cannot tell.

The ATTORNEY-GENERAL, addressing his lordship, said in the interests of his clients he would like the brass box for examination, as there had been some mistake about it. Neither he nor his learned friends would appear in the case if it could be suggested there was any desire to mislead. He asked that his side should be allowed to have the crucible. He thought Prof. Dewar had been misunderstood.

Mr. JUSTICE KAY: You must ask your opponents. Prof. Dewar made a very unpleasant impression on my mind.

The ATTORNEY-GENERAL: Your lordship was good enough to say so; and we are entitled to have the crucible returned, in order that the experiment may be tried again.

Sir HORACE DAVEY: It puts me in a very awkward position. The evidence has been given.

Mr. JUSTICE KAY: I will not do it unless you consent.

Sir HORACE DAVEY: I will not consent.

The application was accordingly refused.

The ATTORNEY-GENERAL intimated that he would not be able to finish the evidence this week.

The Court adjourned at four o'clock.

At the commencement of the proceedings yesterday (Thursday), the ATTORNEY-GENERAL mentioned that he would not be able to finish the evidence on that day. With respect to the evidence of Prof. Dewar, he found he had attached undue importance to the remarks that passed. He was very sorry he did not mention to Sir Horace Davey the application for the box before he did so.

Mr. JOSEPH WILSON SWAN was then called, and his examination and cross-examination occupied the whole of the day. At the termination of the proceedings (which will be fully reported in our next issue), the Court adjourned till Wednesday, the 30th inst., at 10:30 a.m.

THE DIFFERENCE OF POTENTIAL BETWEEN CERTAIN METALS, &c., IN SOLUTIONS OF DIFFERENT STRENGTHS.*

The question of how strength of solution affects the potential difference or (using Prof. Ayrton's abbreviation) P.D. between metals is of importance in making solutions for batteries, also in electro-plating. In this short Paper only a specimen of results can be given, as the space is limited. The solutions used in the experiments now being described were of potassium cyanide (K C N), the ordinary commercial substance being used containing about 60 per cent. of pure K C N. In order to determine the potential difference, a galvanometer was used with a high resistance in series with it. This galvanometer consists of a coil of wire suspended between the poles of a permanent magnet. To the coil is attached a mirror, which reflects light on to a graduated scale. When a current passes through the coil it moves out of its usual position, and the spot of light moves on the scale. The instrument is dead beat, which is a great advantage.

The current from a standard cell (Latimer Clark's) was passed through the galvanometer, and the deflection noticed. There being a high resistance in the galvanometer circuit, it was thus arranged as a voltmeter, and therefore the deflection was proportional to the P.D. between the terminals of the cell. Next, the cell was replaced by the two metals experimented upon, which were dipping into the solution under test. The corresponding deflection was noticed, and, by comparing this with the previous deflection, the P.D. in volts was obtained. Carbon was always used in conjunction with another metal, and the P.D. between them observed when they were in the solutions under examination. The following are a few of the results obtained, the P.D.'s being in volts assuming the standard cell to be correct, *i.e.*, with an amount of 1·435 volt. The figures at the top of each column are the number of pounds of commercial K C N per gallon (1lb. per gallon is equivalent to about 100 grams per litre).

	·005	·025	·25	·5	·1	·2	Saturated Solution. 5·16
Zinc	·925	1·13	1·35	1·395	1·45	1·52	1·615
Copper	·25	·39	1·215	1·27	1·295	1·425	1·535
Brass	·29	·58	1·13	1·21	1·295	1·4	1·46
Platinoid	·435	·535	8·25	·9	·945	1·03	1 185
German silver.	·36	·5	·86	·92	·91	1·05	1·18
Silver	—	·39	6·55	6·95	·76	·845	·97
Lead	·46	·44	·59	·585	·61	·64	·7
Iron	·23	·3	·395	·45	·43	·47	·455

From the above results it will be seen that as the solution increases in strength there is a gradual rise in the P.D. between carbon and the above metals. This is shown better if curves are drawn, having for abscissæ the number of lbs. of K C N per gallon, and for ordinates the corresponding P.D.'s. Other solutions than the above were used—for instance, those of potassium thiocyanate.

It will be seen that the P.D.'s between zinc and carbon and copper and carbon are very nearly alike, so the P.D. between zinc and copper is very small. This is different to what we find in the case of sulphuric acid, where the P.D. between zinc and copper is much larger.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

This Society met on Thursday evening, May 10th, at the Institution of Civil Engineers, Mr. Edward Graves, C.E., the President of the Society, in the chair.

The PRESIDENT: It is my painful duty to have to mention to you the death of the first designer of the Atlantic cable, Sir William Bright, our immediate Past-President. He was known to everyone by the reputation he early acquired in connection with the enterprise of crossing the Atlantic, and of proving that there was no limit of distance to the success of submarine telegraphic connection. His cable had a short life; faults of construction and other circumstances led to its early abandonment, but it showed what could be done, and it taught those who persevered in the same field afterwards both what was necessary and what they should avoid. Associated with the commencement of the Electric Telegraph Company at an early period in his career, he was an active agent in securing its development, and for it he invented the Bell telegraph and other apparatus of great use. In India, in Persia, in South America, in the Mediterranean, in the West Indies and other parts of the globe, he laboured to spread submarine telegraphy throughout the earth. On the morning of this day week he died suddenly; on Monday last he was buried. In him we lost not only a member of much eminence, whose name will be for ever associated with one of the greatest achievements of electrical engineering, but those who were personally acquainted with him, as I was for more than 30 years, lose also a genial and kind-hearted friend. I think, therefore, I am justified in asking you to vote a resolution of condolence, and I beg to move

"*That an expression of our deep regret for his loss, and our sympathy with Lady Bright and the members of Sir Charles Bright's family in their bereavement, be agreed to, and that the Secretary be instructed to convey an expression of the same to Lady Bright.*"

The resolution was carried.

The Risks of Fire Incidental to Electric Lighting.

Mr. W. H. PREECE, F.R.S. (Past-President of the Society), in opening the discussion on this subject, said: We, as electrical engineers, cannot shut our eyes to the fact that the various practical applications of electricity are surrounded with dangers which become of serious moment if neglected, while on the other hand we are perfectly aware that they can be made harmless if we take care to direct the agency we employ in proper and direct channels. We, as electrical engineers, cannot endorse the oft-repeated statement that the electric light is an absolutely safe light. All systems of artificial illumination are dangerous; but of all systems of artificial illumination there is no question whatever about this, that electricity can be made the least harmful. Now, I was one of the first to sound the alarm of the danger of electricity in a letter to *The Times* in the year 1880, and the result of that letter was to bring about my head all those busy promoters of electric lighting that were then so prevalent in this country. Now, the elements of safety are—first, the knowledge of the dangers; secondly, the character of the dangers; and, thirdly, the antidotes to those dangers. The first question that I propose to ask and to answer is this: Where we have systems of this kind full of danger are rules and regulations necessary? There is danger connected with the burning of a candle; but no insurance office has ever issued a rule that you are not to burn a candle at both ends at the same time; nor has any insurance office told us that cats must not be allowed to knock over petroleum lamps, and that it is foolish to place them under the bed. As regards gas, we are not told that pipes must be large enough to convey the necessary quantity of gas, and that gas is leaky, offensive, and dangerous. All these things are self-evident, and nobody would for a moment dream of issuing rules to meet self-evident dangers. But even gas is accompanied with certain dangers. There is a great personal friend of mine living not very far from Wimbledon, who, whenever I have suggested that he should have his house lighted by electricity, has always objected on the ground that it was too expensive. Just recently an explosion of gas occurred in his house, and caused damage to repair which will cost twice as much as if he had had the place lighted by electricity in the first instance. Now, the reasons why rules are necessary for electricity are these:—The agency we use is novel; it is invisible, it is mysterious, it is inodorous. There are very few people—there is not a man in this room knows what it is. We only know how to handle it, but all the world at large feels that there is something in it that they know nothing at all about, and they fear to tread upon it. Electricity is singularly open to fraud. There is nothing so easy as to deceive a person ignorant of electricity of the character of the apparatus and of the materials used to employ it. It is a field for ignorance, and it is, above all things, one in which what our American friends call Cheap Jack-ism is rampant. The result is that rules and regulations are absolutely essential to protect the users of electricity from the rapacity of those who supply it. Now, in 1881 our American friends, the Edison Company of New York, issued a series of rules, and the Fire Insurance Board of New York followed their example. In 1882 the rules that were introduced in New York formed the basis of rules that were issued by the Phœnix Office, under the guidance of Mr. Heaphy, and it is a very curious thing that these rules of Mr Heaphy, with which we are all so thoroughly acquainted, contain even to the present day an American brand upon them in one particular rule, and that is the use of the word *ground* as applied to an earth-current. Now, the Society of Telegraph-Engineers, at the same time, in 1882, took up this subject, and we brought out rules that are familiar, no doubt, to many of you; and, also at the same time, the Franklin Institute of America did the same thing. From 1882, or 1883, things in England had been going on very pleasantly indeed. The rules that were issued by the Society of Telegraph-Engineers were virtually an assertion of certain principles. The rules that were drawn up by Mr. Heaphy were drawn up in the interests of the fire offices, and they are virtually detailed rules that have been the guidance of I think nearly every telegraph-engineer amongst us. Personally I can say that I have never used any others. But last year an alteration was suggested. Someone started a hare, and that hare has been running rather fast since then. Not only has the Society of Telegraph-Engineers been carrying out the work that it is my duty to detail to you to-night, but others have stepped into the breach. We have at the present moment rules issued by three independent offices, and the cry is, "Still they come." Nevertheless, with numerous rules before us, and the prospect of rules to come, we are not so badly off as they are in the United States. In the United States there are the rules drawn

Digitized by Google

up to which I referred just now by the New York Board of Fire Underwriters. Those rules, originally drawn up by Mr. Woodbury, have from time to time been revised, and they have kept pace with the advances in electric lighting; they are short and concise, and, as far as the practice in New York is concerned, they meet every requirement. At Boston the Fire Underwriters' Union have done the same thing; there is a capital series of instructions drawn up there. But in New England there happens to be another insurance body, with head-quarters at Boston, who have drawn up rules and regulations, and these rules and regulations number as many as 72. At Philadelphia there are again rules and regulations drawn up by the Franklin Institute, and there is scarcely a town of any size or consequence in the States, with the exception perhaps of Chicago, that has not got its own rules and regulations. So that these poor Americans are considerably worse off than we are. In the spring of last year it was suggested to the Council of this Society that the time had arrived when the rules and regulations of the Society should be revised, and a committee was formed to deal with the subject. I may tell you that the rules and regulations of this Society were prior to that in very considerable demand. Some thousands of copies had been issued, and at the very time when we were asked to reconstitute the committee a demand had arrived from one of the large provincial offices for 200 more copies. Indeed, from inquiries I have made I have not the least doubt that there have been a greater number of installations in this country put up under the rules and regulations of this Society than under those of the Phœnix Fire Office. Of course, in London the Phœnix Fire Office has been paramount, and I think no other rules have been used; but it is not so altogether in the provinces. In May last this committee was formed, and I may tell you at once that the re-formation of this committee did not meet with my personal approval. I was not present when it was discussed, but the committee did me the honour to elect me as their chairman, and as I had been chairman of the previous committee I felt bound to take the matter up, although I was perfectly satisfied with things as they were, and we had found that the rules issued by the Phœnix Fire Office were very complete. We had found that the well-known inspector of the Phœnix Fire Office was always and ever ready to meet us on every occasion. I have been brought into intimate connection with him in connection with the exhibitions, and especially with the Colonial Exhibition. But still, there was a demand that their rules should be revised, and our very first action was to get our secretary to call upon the fire offices' committee to see how far any movement on our part to reconsider these rules would meet with their support and approval, and to intimate that this Society had no desire to move in the matter unless they could be assured that their doing so would be of service to the insurance companies generally. It having then been decided that some steps should be taken, it was perfectly evident that there ought to be only one set of rules in existence; and there being as it were two powers in existence—that is, the Society of Telegraph-Engineers and Mr. Heaphy—I came to the conclusion that the only satisfactory method of bringing matters to a crisis and settling them satisfactorily was to get Mr. Heaphy to act in conjunction with our committee. Mr. Heaphy joined the Society. We had numerous meetings; all through the months of May and June and July we were at work. We formed a small sub-committee of Mr. Crompton, Mr. Siemens, General Webber, and myself, and we met Mr. Heaphy, and matters were going on as swimmingly as one could wish. But, unfortunately, there was a little cloud in the horizon that we had not anticipated. We found, when we brought these gentlemen connected with the fire offices together that it was like an attempt to mix oil and water. It was the signal for a storm, and the result was general electrical disturbance (laughter). We had arranged that the original rules drawn up by the Society of Telegraph-Engineers should be revised to date, and be simply generalities; that they should be followed by detailed rules to be called the Fire Office Rules, which were, as a matter of fact, the rules drawn up by Mr. Heaphy. But there were certain points connected with these rules that did not quite meet the approval either of myself (as chairman) or of the members of the committee. There is not one word to be said against the matter of these rules; the objections were to the phraseology, to the mode in which they were drawn up, to the fact that after a rule had been defined clearly there was the proviso that it might be departed from "with the approval of the inspecting officer." In fact, the inspecting officer was made too much of an arbitrator in the matter, whereas we rather desired that the rules should be hard and fast rules, only to be departed from under very exceptional circumstances. But the *crux* that we broke upon was this. It was proposed that the rules should be preceded by words to this effect: "The following detailed rules having been drawn up by the Phœnix Fire Office for electric light and electrical power installations, and having been laid before this Society for its approval, are recommended for general use." Now, we had not been through these rules. Mr. Heaphy insisted that we should come to a decision that these rules were approved by us before we had examined them; and, as chairman of the committee, I decisively and decidedly declined to put any such proposition before the committee. Mr. Heaphy thereupon left the committee, I am sorry to say, and we came to grief. Now, when you are in trouble the best thing to do generally is to adopt the policy of masterly inactivity. At this time very conveniently the holidays arrived. But in December we had to commence again. It was necessary to carry out our determination to draw up rules of our own, and accordingly we set to work, and in March our rules were issued. Now, certain offices object to these rules even as they are, and we have not yet succeeded in convincing all the fire offices either that they would be wise to accept our rules or that they would be wiser to accept those of the Phœnix Fire Office. Mark you, this question of rules and regulations is entirely a question between the insured and the insurers. We can only act in the capacity of "guides, philosophers and friends": we cannot attempt to force rules upon anyone, and there is no such thing, in drawing up rules of this kind, as (what has been sometimes complained of) either professional dictation or the interference of busybodies. It cannot be said for one moment that the action of this Society in this business has been anything but one dictated by their sense of duty. The work of the committee is an extremely difficult one. Our committee was formed of the strongest men that we could find, representing science, the consulting element, the contracting element, and the users. We had Prof. Adams, Prof. Ayrton, Mr. Crookes, Prof. Foster, Dr. Hopkinson, Prof. Hughes, and Sir William Thomson. We had representing the consulting interest Sir Charles Bright and his brother, Prof. Forbes, Mr. Gordon, Mr. Massey and others. We had Mr. Crompton, Dr. Fleming, Mr. Siemens and others. You could not have had a stronger committee. I will just give you a few instances of the work we had to do. Take, for instance, the first rule drawn up by the Guardian Assurance Company; I am not quite sure whether it was drawn up originally by the Guardian or by the Westminster. The rule is, "The dynamo machine must be placed in the engine room or in a compartment separated from and not communicating with any room in which inflammable material is manufactured or stored." Now one member will get up and exclaim, "Where is the idiot who would do such a thing?" Another member will want to know where the dynamo should be placed except in the engine room. Another member will say, "Why, this rule is clearly drawn up to avoid plagiarism;" and he will call attention to Mr. Heaphy's rule, which runs, "No dynamo, motor or any apparatus for generating electricity to be placed in any working room of any cotton, woollen, flax, jute, or corn mill, or in any mill or factory of a like description, or in any working room or place where any hazardous process is carried on, or in which any hazardous goods are stored, or where there is special risk, unless permission to the contrary be given." Gentlemen, that rule at any rate, without the last addendum, is written evidently by somebody who knows what he is writing about. Now let me read you our rule—Rule 29. "Dynamos should always be fixed in dry places, and they must not be exposed to dust flyings or any other industrial waste products carried in suspension in the air; they should not be permitted in the working rooms of mills, where the liability to such danger exists, or where any inflammable manufactures are carried on, or inflammable materials are stored." So that after expending, perhaps, one day over a rule like that, we at last get phraseology that satisfies everybody. I have here all the rules,* and perhaps it would be well to print them in our *Proceedings*, but it would take up too much time for me to refer to them in detail.

Let me take first of all a few cases that we want to legislate against. A short time ago there was a paragraph in all the papers that Lord Brassey's house was on fire, and that it was due to a secondary generator. Now, there is no doubt that the alarm of fire was due to a secondary generator; but that secondary generator was fixed in a fireproof box; it was new; it warmed up a little bit, and smoked a little; the smoke was seen to issue out of the fissures of the box. You have heard that when Sir Walter Raleigh was first seen smoking the servant threw a bucket of water over him, and I have no doubt in Lord Brassey's house the servant poured water over this box; but there was no fire at all. And yet that simple little fact has done more mischief than anything that has happened in the mind of those who were contemplating using electricity. At Boston there was a theatre, the Temple Theatre, lit by electricity. From some cause a short circuit was formed between two wires of cotton; the spark was seen; the people in connection with the theatre at once took up the boards and discovered the flame, but before they could do anything the flame rushed through the flooring owing to the extremely inflammable character of the place, and the theatre was burnt down. Not very long ago, nearer home, at Derby, in the stores of the Midland Railway, a short circuit took place through using a tin shade to a lamp; it was one of those wretched old wooden holders, which I hope now are entirely out of date: this burned, the wire caught fire, and it took some trouble to put it out. Then there was a case at the Parliament House at Brussels, fortunately trifling. There was another case of the Star Theatre at New York. There was another case at the Porte St. Martin Theatre in Paris. But while the numbers of accidents due to fires can be counted on our fingers as regards electricity, the list of fires in the year 1887 in theatres and places of amusement which were entirely destroyed and where there was terrible loss of life averaged two or three per month. Now, wherever we have electric lighting there are serious risks that we must protect ourselves against—risks little anticipated by the users. For instance, in stables, who would imagine that the ammonia issuing from the excreta of the animals will attack the wire and the metal staples that are used, and produce accidents? Who would think that the mere washing of the floors would lead to a fire unless attention were strictly called to it? And among those who are not in the habit of using electricity, who would think that rats and mice are perhaps the greatest enemies that we have to contend with? Then again, there is another convenient and useful mode of fixing wires in houses whilst the houses are being built, and that is to bury the wires in the cement, but there is no more foolish and dangerous practice. Again, moisture in any shape or form must in houses, sooner or later, become a danger. In underground work, in cable work, in crossing streams and oceans, water is our safeguard; there is not an instance I know of where gutta-percha has deteriorated in water; but where you come to place india-rubber or gutta-percha indoors, where it is subject to changes of temperature and attacks of moisture, cracks are sure sooner or later to occur in the insulating medium; moisture enters; leakage takes place; the water is decomposed by the current; we have electrolysis; we have the conductor attacked, and sooner or later there is a breakage in the conductor; we have an arc formed, the insulating medium takes light, and fire will result. It is very doubtful, indeed, whether we are adopting a wise practice in encasing our wires in wood. It is dangerous to use a wood casing anywhere where the wood is subject to moisture. I have on the table a most

* See *The Electrician*, April 13, 1888, p. 638.

Digitized by Google

interesting example of this taken from a ship. There have been three or four cases where the wood has taken fire on board a ship. The specimen on the table is well worth your serious examination. The wire undoubtedly is very poor wire; nevertheless, moisture fell from it; leakage took place; a short circuit of a kind was formed; the fuses did not act, but the fire occurred. Where you have a steady leakage through moist wood of that kind it is a current of low intensity; the fuse does not act, a fire takes place, and the mischief is done. There is another cause of danger I cannot too strongly urge and put my veto upon as far as I possibly can—not so much on account of its danger as on account of the accidents, sooner or later, sure to be inflicted on the lighting, and that is the use of mercury. In an experience of thirty-five years I have never known a single instance where a mercury contact did not sooner or later create mischief. Unless mercury can be renewed every day or every week, or frequently, it must sooner or later lead to mischief; and I have even seen fires (at least, I remember, at any rate, one fire) due to a mercury

FIG. 1.

contact. There is another very serious cause of accident in houses fitted up with electric light installations, and that is the temptation which the charm and the comfort of the light gives to those using it to extend their system, to take their wires to extra rooms, and eventually to call upon their conductors to carry more current than they were originally designed to carry. But of all sources of accident there is nothing so serious and dangerous as bad joints and bad connections. On this point of joints the practice is very careless. All old stagers will say that no joint can be perfect unless it is soldered. Yet I find in one of the Boston rules these words:—"Joints in wires to be securely made and wrapped with tape; *soldered joints are desirable, but not essential.*" I take that to be fatal to those rules. Again, with soldering, there is a very curious difference of practice with regard to the flux to be used. In one of the American rules, the New England rule, it says, "Resin must not be used as a flux." In Mr. Heaphy's rules, he says, "Resin should be

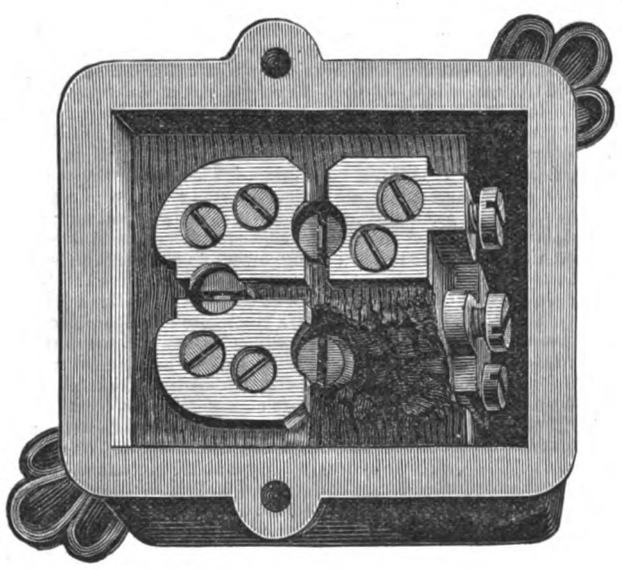

FIG. 2.

This figure shows the base of a damaged switch, which nearly set the Houses of Parliament on fire.

used when soldering." In our rules we say, "When soldering fluids are used in making joints the latter should be carefully washed and dried before insulation is applied." As a matter of fact, in these points we must be guided a good deal by experience, and we have found by experience that the fluids make better joints than resin. In the Post Office service we make it a rule that all joints on aerial copper wires should be made with what is known as Baker's fluid, which I believe is zinc chloride. I have never had it analysed, but it is an admirable flux, and one that certainly makes a better joint than resin or than anything else I know. The next great source of trouble is loose connections. I mentioned in this room once before that in an installation that I had something to do with there were no less than 6,000 places where sooner or later, owing to the vibration of the building, the screws must shake out and the joints become loose. Every one of these 6,000 connections sooner or later is bound to generate heat and to do harm. Cut-outs have formed the subject of a paper so recently that I need scarcely refer to it; but we know very well from experience that cut-outs are a source of danger rather than a source of safety unless they are properly looked after. Switches are a source of danger if they are not properly looked after from these very loose connections. I have here (Fig. 2) an extremely interesting switch; it is one of the Edison pattern. It was put up in the House of Commons, I think in the year 1882, and it was very nearly the cause of another fire in our Parliament Houses. A connection at the back became loose, and heat was generated; fortunately it happened during the time people were about, and it was seen in time. It is a case that merits your careful examination. Another great point is the question of the character of the insulating medium. What we want is something that shall act as an insulating medium, and at the same time be non-inflammable. Now, it unfortunately happens that gutta-percha, india-rubber, paraffin in all its forms, resin, resin oil, bitumen, nearly everything is of an inflammable character. I have recently been trying some wire that is used to a very large extent in America by the Westinghouse Company. That company use a wire known as Waring's. Now, the material that is employed as an insulating medium is one of the distillates of the petroleum oil. This residue is a hydro-carbon, but you will find that it is hardly possible to set it on fire. I have some samples of it here. I have been experimenting with it with currents, with flames, and I have not in one instance succeeded in setting the stuff on fire. It is the least inflammable material that I have come across.

These, gentlemen, are the principal dangers that we have attempted to meet. We cannot say that altogether we have met with very great success. The value of a man's work is very often estimated by the amount of criticism that it engenders, and where it is the fashion, as, unfortunately, it is in this country, to criticise everything that is done by a Government department or by a corporation like ourselves, we do not estimate the value of our work by the number of criticisms, but by their value. During the whole time that this rather heavy and arduous work was going on letter after letter appeared in the press. These silly and senseless and foolish letters were of course always anonymous, and I do think that the anonymous letters in our papers, especially our technical papers, is a very unfortunate practice. All these letters were written on the assumption that the existing rules were put forward as perfect. I say the existing rules were very good; I cannot say too much in the praise of the work that has been done by the Phœnix Fire Office. I think the way in which the Phœnix Fire Office rushed into the breach and accepted transformers before we electricians did speaks very highly for the pluck of that office. There is nobody who has had such fortunate opportunities to acquire experience as Mr. Heaphy has, and he has taken advantage of them; his rules are revised month after month and year after year, and all Mr. Heaphy's experience is embodied in them, but still, they are not perfect. The committee of the Society is virtually broken up; but speaking for myself personally, I should be very glad indeed to see the work that we have tried to do started afresh from the point where we broke off. I think there ought in this country to be only one set of rules, which rules shall embody the general principles enunciated by this Society, and also the detailed rules which have been accepted by all the fire offices. I do sincerely hope that something will be done to have only one set of rules. I look upon the rules brought out by the Westminster Office and the Guardian Office as a disgrace to those offices; they have been drawn up with an amount of ignorance that is most regrettable. For instance, there is one of those rules which would admit into our buildings the very worst description of wire that I have ever seen; and there are several other rules that ought to be expunged. I hope that those offices will reconsider these rules, and abandon them as soon as possible. I should like to call your attention to our own rule which specifies the insulation resistance. I will read it to you:—"(16.) The installation of a system of distribution should be such that the greatest leakage from any conductor to earth does not exceed one five-thousandth part of the total current intended for the supply of such lamps." If you specify that the capacity of your conductors shall be 150 megohms per mile, who is to find that out, and who is to test it? If you say that your leakage from all causes shall be one five-thousandth part of your maximum current, you have something you can examine, something to work to, and something that every man can test. If he has 5,000 lamps one lamp is a capital detector; if one lamp is illuminated by leakage, the rule is not complied with, and you must see where the fault is. But the chief precaution, and the last precaution I shall bring to your notice is this—the proper education of our coming electrical engineers. I want the education of our young engineers to be very carefully watched, so that they do not grow up with false ideas and false notions. The chief element of danger is ignorance, and another danger is the terrible competition that exists in electric lighting. The curse of electricity is the jerry builder, the man who puts in a tender for a contract at a price which he must know will not pay him, and which obliges him to use imperfect materials, in the hope of getting his reward by having to put in "extras." These are the sort of people we want to meet by issuing rules and regulations. We want to put a stop to cupidity and bad work, and to see that everything is properly carried out. In drawing out these regulations I think the Society of Telegraph-Engineers has only done its duty, and I hope and trust that while this meeting will not for one moment withhold any just and fair criticism, it will not be imagined that the Society has been actuated by anything else than a desire to put electric lighting on a proper footing. The Society has not stepped forward to bring out these rules with the idea of securing notoriety. The healthy and charming luxury we all wish to see in everybody's house has so far been retarded by a struggle for existence, especially on the part of those who wish to earn a living by erecting structures. If they will only follow these rules and regulations, then whatever fear there may be at the present moment that electricity is dangerous will disappear entirely, because all source of danger will have ceased. Mr. Heaphy has told me that there never has been one single instance of a fire in any installation that has

Digitized by Google

been carried out under his rules, and I believe that to be absolutely true; and I am perfectly certain that if the rules and regulations of this Society be followed in the same way, and the work of inspection is done with the same care, there will be no accidents in this country to lead people to imagine that electric lighting is dangerous.

Mr. HEAPHY, after thanking Mr. Preece for the kind and flattering way to which he had referred to the rules of the Phœnix Office, said that he would next week enter into an account of the differences that had arisen between himself and the Rules and Regulations Committee of this Society. As to Mr. Preece's suggestion that the committee should recommence their work, he would point out that during the long negotiations that had been gone into no difference had arisen upon one single point in the rules themselves, but the whole dispute had arisen about the mention of the word "Phœnix." If that word had been adopted there would have been no trouble, and none of this issuing of rules in all directions, whether by competent or incompetent men. With regard to transformers, they would all remember the fear and timidity that were aroused in this country when transformers were about to be introduced. The matter came before the Phœnix Fire Office, and that office did not adopt any hesitating policy, it did not wait to see what other offices would do, but it decided the matter for itself; it took the risk, and a very great risk it was. It stated publicly that transformers and high-tension currents might be admitted into buildings under certain regulations, and that without any extra charge to the consumer. That policy had been thoroughly successful, and the old ideas as to the danger of transformers were exploded. It was all very well for other people now to come and bring out rules about transformers, after the Phœnix had borne the brunt of the experiment, and had risked a considerable amount of money as well as reputation. However, he felt assured that the Phœnix Office would be only too happy and willing to meet the Council of this Society in every way, and resume the work that had been interrupted, provided that the point upon which they had differed was amicably settled.

Mr. HEDGES said that the rules drawn up by Mr. Heaphy seemed to be very admirable; but he could not understand why the Phœnix Office should put on them the extraordinary word "copyright." There could be no copyright in those rules. A Paper was read at the Society of Arts in May, 1882, by Mr. Thomas Bolas, at which the risks incidental to the electric light were discussed. At the very time he had received from America a set of rules which had been drawn up by Mr. C. J. Woodbury, which were in substance the same as those now put forward by Mr. Heaphy. There could be no copyright in rules which had been imported into this country, and which were the work of another engineer who had done good service on that side. He would like to see one set of rules framed which should be adopted by the Fire Risk Committee governing all the insurance offices.

Mr. NEWMAN, as one who had had a great deal to do with the preparation of the Guardian and Westminster Office Rules, observed that whatever merit or demerit attached to those rules they had been brought out for a specific purpose, and they had to a certain extent answered that purpose. Things had arrived at a very unsatisfactory state. For a long time they had been hoping and waiting for a set of rules from this Society which would guide the insurance offices in framing their own regulations, and at last it was felt that the matter would be best brought to a head by issuing a set of rules for use in their own offices. In some quarters it seemed to have been thought that no office had a right to issue rules of its own, but was obliged to adopt rules which bore the stamp of another office. He trusted that the rules which had lately been issued by this Society would pave the way to a better understanding amongst the offices generally, and that before long a set of rules would be issued and accepted by all the offices; but whatever might be the fate of the rules prepared for the Guardian and the Westminster Offices, the gentlemen who had to do with the drawing them up would feel that they had done something towards putting an end to what was an intolerable state of things.

Mr. SWAN thought that Mr. Preece's enumeration of the dangers incidental to electric lighting was a very useful one. He remembered that when incandescent lamps were first shown in that room Mr. Preece, who was in the chair, sounded the alarm about fire risks, and at that time he (Mr. Swan) considered the note was pitched too high; but he was bound to say that he did not think so now. He quite agreed that one of the principal dangers to be guarded against was ignorance.

Mr. JOHN VERITY said that the matter of these rules was essentially one for the insurance companies; all the Society could do was to frame a set of rules, and endeavour to influence all the offices to adopt them. There was naturally some rivalry between the insurance companies, but it seemed to be undisputed that the Phœnix Office had led the van. After all the trouble they had had about transformers, they at last began to understand them, and it would be very regrettable if some means were not found of arriving at a set of rules which should be adopted by the Phœnix and the other offices. After what had fallen from Mr. Heaphy and from the surveyor to the Guardian Office, he trusted that the committee would meet again and amicably settle all their differences.

Mr. MANVILLE pointed out that on the committee there were only two contractors. As this was eminently a matter between the contractors and the insurance companies, the contractor element ought to be strengthened. He quite agreed with Mr. Preece that all joints should be soldered, although a consulting engineer of the first standing had told him that he disbelieved altogether in soldered joints.

Mr. PREECE: I hope he was not on the committee.

Mr. CROMPTON referred to the work which had been done by the contractors on the committee in preventing uselessly stringent regulations from being embodied in the rules. As to Mr. Heaphy's position, it seemed to him that after all the hard work that gentleman had done, and after his taking the risk of countenancing transformers and high-tension currents, there was some ground for his claim to, at any rate, a sort of moral copyright in these rules. He was perfectly certain that if a poll were taken of the electric lighting contractors, 95 per cent. would be in favour of adopting Mr. Heaphy's rules and no others, and any little advertisement which would be given to the Phœnix Office by the general adoption of their rules would only be what they had well earned. It was a matter of common fairness that the other offices should give way in this matter.

Mr. SIEMENS said that the main defect which existed in Mr. Heaphy's rules was the saving clause which applied to nearly every rule, giving the fire office inspector power to grant permission for the rule to be departed from. So far, of course there had been no complaint to be made as to the working of that proviso, because Mr. Heaphy himself was so perfectly fair to the contractors, and open to meet them in every legitimate way; but who was to say that Mr. Heaphy's successor would be equally fair and conscientious? What was wanted was definite and hard and fast rules.

The discussion was adjourned till the following Thursday.

STUDENTS' MEETING.

At a meeting of the students of this Society, held on May 3, Mr. W. M. Mordey in the chair, Mr. E. J. RYVES read a Paper on "Electric Welding," of which the following is an abstract:—

Some attention has lately been drawn to the subject of welding by means of electricity. In America Prof. E. Thomson uses an exceedingly heavy current at a low potential, and his method of obtaining it is by means of a transformer, by the use of which he can reduce the heavy current-circuit to a foot or eighteen inches in length, thus making a large saving in copper as well as avoiding the great loss in conductors, from which it is so difficult to escape when using large currents. In this system an alternate-current dynamo is connected to the primary coil of the transformer, while the secondary circuit is completed through the two pieces of metal to be united. The primary circuit of a welding set with which I assisted in making some experiments not long ago consisted of 30 yards of No. 16 B.W.G. c.c. wire, wound in a coil 6 inches in diameter, around which and in the same plane was bent a thick copper bar about an inch and a-half in diameter, and which terminated in massive pole-pieces which held the pieces of metal to be joined; these could be made to approach each other by means of a hand screw so as to bring pressure to bear on the heated join. Both the primary and the secondary coils were completely covered by a quantity of iron wire. We managed sometimes to obtain very fair welds, though the majority of the attempts we made were failures, due probably to want of experience. The joins looked very good from the outside, but were easily broken. The specimens which Prof. Forbes has kindly lent show, however, what can be done by this process. Another method of welding by means of electricity is that of M. Benardos, which I have had better opportunity of examining. Last summer I went to St. Petersburg for the purpose of seeing what his welding was like, and I am sorry to say that I was rather disappointed with what he could do. I unfortunately let him know this, which brought my visit to an end sooner than I intended, as he would not show me anything more. On first entering his works I was shown specimens of welds done by his process, which, as far as external appearances went, were perfect; some of these were of fair size, the area of join being in some cases six or eight square inches. As I had not seen these made I could not bring them home as specimens of his process, but I had taken the precaution before I left London of having several pieces of wrought iron, mild steel, &c., cut for me, in order that I might have them welded and afterwards tested; these were all stamped to prevent others being substituted for them. The current necessary for his process was derived from 150 Benardos accumulators, arranged in three parallel groups of 50 each, and which were charged at about 60 amperes for 10 hours a day. The dynamo was a shunt-wound Siemens pattern, and was capable of giving a maximum output of 18,000 watts (150 volts, 120 amperes), and was driven by a 25 horse-power steam engine. The total capacity of this battery was 360 ampere-hours, at a potential of about 100 volts. The welding table consisted of a massive iron slab resting on wooden supports, and which was connected to the negative pole of the battery; the pieces of metal to be welded were laid on this table. A carbon rod varying from 13mm. to 26mm. in diameter (according to the size of weld to be made), and fixed in a suitable holder, was connected by a flexible cable to the other pole of the battery. The required temperature is obtained by starting the arc between the carbon rod and the metals to be joined, which are on the welding table. The current must have been very great, as there was seldom any resistance in circuit, and except when welding small pieces of metal four-fifths of his battery were switched on. The different experiments which were done for me included the welding of wrought iron to wrought iron, cast iron to cast iron, mild steel to mild steel, wrought iron to tool steel, drilling holes in iron and steel, &c. None of these welds were really good, as the specimens on the table show. His method of going to work is briefly this: the ends of the metals to be joined are first of all melted down, then (if steel or wrought iron is being operated upon) pieces of wrought iron are placed on the join and melted in by the action of the arc. If welding cast iron or copper the process is the same, except that cast-iron and copper scraps are added respectively. When welding steel or iron, M. Benardos used a mixture of sand and lime as a flux; when copper was one of the metals the flux used was borax. In nearly every case the metal was badly burnt and spoilt by the excessive heat. This seems to be unavoidable, and is the great fault made in welds made by M. Benardos' process; in Prof. E. Thomson's method, of course, the temperature can be regulated to a nicety, and it thus has a great advantage over the other process.

Mr. MORDEY said the Paper, although a record of failures, was not less interesting or useful on that account. He thought that many of the failures made by persons who had experimented with electric welding were probably due to the fact that they were not sufficiently acquainted with

Digitized by Google

ordinary welding, in which, perhaps, they would not have been much more successful. The amount of power used by M. Benardos was out of all proportion to the effect sought, and on this score the process of Prof. Elihu Thomson has a distinct advantage. A probable application of the latter method would be in heating and soldering—not welding—the joints of large conductors for street mains. He knew of no other process by which such an operation could readily be carried out. By this method it was possible to heat up a joint very quickly and to localise the heat.

Mr. G. H. HUME drew attention to the fact that electric welding had been used some three or four years ago by Messrs. Siemens for jointing rails at the Ryde pier.

After some remarks by Messrs. MARSH and HAYNE, Mr. RYVES replied.

Specimens of Thomson's electric welds were lent by Prof. Forbes, to whom the thanks of the meeting are due.

A vote of thanks to the Chairman concluded the meeting.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 5th*, 1888.

The New York newspapers are amusing themselves just now by working up a scare on the subject of arc light wires. The basis of their clamour is an accident which happened last week in the Bowery, which, as may perhaps be known to some of your readers, is a very busy thoroughfare, combined in equal proportions of Ratcliffe Highway, Tottenham Court-road, the Upper-street, Islington, and the Borough-road. This great artery of traffic glitters every night with hundreds of arc lamps, and without a question there are more arc lights, many times over, to the mile than can be found in any other street in Christendom. Some of the stores and music halls have lights dangling in front of them from roof to street a dozen at a time, and the eye is positively wearied with the brilliancy of the scene. All the small storekeepers, too, indulge freely in arc lighting as a means of advertisement, and as a number of these stores are low pitched, it happens that the lights in some places come much nearer the level of the passers by than is prudent. In one of these stores a young German was in the playful habit of flipping the arc lamp with his finger every night as he left the place, his object being, as he was accustomed to explain to his less daring friends, to secure the benefits of "a free shock." What happened exactly on this particular occasion is not known, but on reaching up to touch the lamp he was instantly thrown back, and when picked up was dead. This suicidal performance has been followed by a howl for the burial of the arc light wires, though how the undergrounding of the wires will prevent such occurrences is more than I or any other electrician can make out. It would, of course, be better to have the lamps so thoroughly insulated that nobody could trifle with them, even if he insanely wished to do so, and it would also be better to have the lamps at a greater height above the sidewalk, though here, again, the efforts of the lighting company to maintain a proper altitude for the lights are frustrated by the desire of the storekeepers to have the beams penetrate to the innermost recesses of their various places of business. I mention the details of this affair because it is probable that distorted versions from the daily papers may reach you, and be made the text for very absurd moralising. If our friends in England have any means of preventing lunatics from trying to use arc-light currents, directly applied, for therapeutic purposes, we shall be glad to know it.

The introduction of electric motors is proceeding apace, and one hears of their being installed on every hand. The rapidity of their introduction in some Western towns is really remarkable. In Des Moines, Iowa, there are now twenty-five in use, and as many more are expected to be put in this year. At Oskaloosa, Iowa, every printing press in the city is run by electricity. At Topeka, Kansas, the Edison Company has thirty-one motors on its circuits, averaging 120 horse-power, and several new business blocks that are being built are having 10 horse-power motors installed for operating their elevators. At Los Angeles, California, a big power plant is being erected, with a telegraph engine power, it is said, of one thousand horse. At Davenport, Iowa, a plant of 100 horse-power for stationary motors is to be put in, in connection with the new electric railway, and the same is also being done at Lafayette, Ind. One of the most striking Western installations of electric power is that in the new flour mills at Laramie, in remote Wyoming. This mill has been built without any engine or boiler-house, and the sole provision for power consists in two Sprague motors of 25 horse-power each. The capacity of the mill is 100 barrels of flour per day. One motor drives all the purifying and wheat cleaning machinery, and all the elevators and conveyers, which, strung out in a line, are over a mile in length. The other drives seven double sets of rolls and the flour packers. The current is supplied from the local Edison station, on the three-wire system. The manager of the mill maintains that he has a lower percentage of loss of engine power this way than he would have with an engine placed directly in the mill, and having to deliver its power by long lines of shafting and heavy belts. This mill has now been in operation some little time, and the success has been so great that another has been ordered for another Western city. At Laramie, too, a 20 horse-power motor has been placed in the rolling mills. It runs about 120ft. of 3in. shafting, with many heavy pulleys, driving 4 spike machines, 2 boltheaders, 2 nut pressers and a large quantity of thread-tapping and other machines. It is said that before this motor was placed the power had to be transmitted nearly 300ft. by belts and shafting, and that nearly 50 horse-power was required to do the same work; while, on the other hand, the men are doing one-half more work than they did under the old system, owing to the fact that very often through low steam the speed was so slow that the machinery had to be shut down. It will be seen that in the West, where several of the places which have introduced electric light never expect to see a gas plant, the use of the current for power as well as light is gaining at a tremendous pace. Here in the East, however, we are not at all remiss in this respect, as new installations of moters are recorded daily. The Thomson-Houston Company this week, for example, has received an order for an electric power plant of 50 horse-power for New Bedford, Mass., the motors to range from $1\frac{1}{2}$ to 7 horse-power. Here in New York the call for motors is quite brisk.

The American Bell Telephone Company is now enjoying the effects of the recent decision in its favour by the Supreme Court in the shape of one or two minor victories. At Little Rock, Arkansas, Judge Brewer, of the United States Circuit Court, has granted an injunction shutting up an opposition exchange, on the ground that the decision of the Supreme Court was final and conclusive in this matter, and it was needless to consider or discuss the subject from any other point of view. At Baltimore, also, a perpetual injunction has been obtained against the Pan Electric and the Washington Telephone Companies. Meantime, there are various mysterious reports as to the activity to be shown in pushing the Bonta and other "make and break" apparatus; but, so far, the talk seems to be done very much for the purpose of booming stock.

A very interesting evening was spent on April 27th by the New York Electrical Society at the Stevens Institute of Technology, when Prof. A. M. Mayer demonstrated by some exceedingly novel and simple apparatus the laws of static electricity. The apparatus he employed he had contrived himself with accustomed ingenuity, and it consisted of a pendulum suspended from the ceiling, employing gravity as the opposing force instead of torsion as employed in the Coulomb torsion balance. This pendulum swung in front of a scale, and by very simple calculations one was thus able to see and measure the attractive and repulsive force exerted between charged bodies. The same apparatus demonstrated the law of the dispersion of electricity, which was shown to agree with that of heat. Prof. Mayer gave also ocular demonstration of the specific inductive capacity of different bodies. This he did by taking plaques of the various substances, such as glass, paraffin, rubber, &c., placing them between two charged plates, and measuring the difference in distance between the two necessary under such conditions to bring about equal attrac-

Digitized by Google

tion. The lecture was delivered with all Prof. Mayer's well-known ease and charming manner, and with the suggestiveness which some of your readers may perhaps remember in his address which has long had a great reputation here on "The Earth as a Great Magnet." The guests of the evening left the Institute with a far more vivid idea of the law of inverse squares, of the value of the dyne, and of other points than they ever had before, and many of them were impressed with the fact that there was still a great deal to be done and observed in the neglected field of static electricity.

Turning to matters of gayer import, I may note the formation here of the Magnetic Club, which affords evidence of the strong fraternal feeling existing among the telegraphers in this city. This club sprang out of a little dinner held recently by a number of the prominent members in the various co-operative associations of telegraphers, and has now started on its career with bright prospects. The club presents one or two novelties in its plan. It is proposed to have four social gatherings a year. The dues are only nominal, but the expenses at each of the four meetings are to be shared *pro rata* among those who actually attend. In this way no member is burdened unless he participates actively, and then his enjoyment costs him no more than it costs anybody else. There seems to be a good point in this, and I have no doubt that the quarterly gatherings will be extremely pleasant and well attended. The first president of the club is Mr. C. P. Bruch, who has done so much to make the success of the Telegraphers' Mutual Benefit Association, of which he is secretary—a body which has now paid out in death claims to the *beneficiaries* of its members the sum of nearly £75,000. The first vice-president is Mr. W. J. Dealy, whom, no doubt, many English visitors to this country remember as the suave and energetic manager of the big operating room of the Western Union Company, 195, Broadway, where, according to Dr. Norvin Green, the staff is in such excellent condition under private management that it does nearly twice as much work as it would do under a Governmental *régime*.

CORRESPONDENCE.

THE MALTA-ALEXANDRIA CABLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the letter I addressed to you last week, I find that through inadvertence I omitted the word "electrical" when referring to the Malta and Alexandria cable of 1868, thus making it appear that I had sole charge of that expedition on behalf of the manufacturing company, instead of the electrical charge only. The cable was successfully laid under the personal superintendence of Sir Samuel Canning, I being responsible for the testing and working. It may not be generally known that this cable passes through a depth of over 2,700 fathoms, giving another illustration of the practicability and superiority of deep-sea telegraph cables over those laid in comparatively shallow water—a subject which was being much discussed in those days. I believe the cable is still in the same condition electrically as when first laid.

Perhaps you will permit me to say in reply to the letter of Mr. Graves, in the same issue, that his version of the meaning of the word "touch" may be the correct one; but, unfortunately, all the readers of the "Papers of Fleeming Jenkin" are not so well up in our technical terms as he is.—Yours, &c.,

May 12th, 1888. WILLOUGHBY SMITH.

ELECTRIC OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Dr. Fleming's valuable communication on this subject owes a good deal of its interest to the manner in which it completely accounts for a number of well-known phenomena, such as those of demagnetisation and the unpleasant discharge from a Leyden jar when a glass handle is not used for the discharger. Prof. Hughes drew attention some time ago to the "period variable" during which the resistance of a conductor is much higher than its ordinary ohmic value. Some further information on the actual period of the oscillations would be interesting, for it appears that they are by no means so small as to be negligible. A dynamo with a commutator of 120 sections, running at 1,100 per minute would have a period of $\frac{1}{2200}$ second for each section. This would correspond to one and a-half periods of $\frac{3}{10000}$ second, or the instant corresponding with the first minimum. The fact that the brushes cover more than one section would prevent this from having any material effect, but it is worth noticing that the periods are not so small as to be entirely neglected. I have noticed on several occasions that a shunt dynamo will not excite if one brush be removed and contact with the commutator be made with the end of a wire; no doubt in this case other considerations are introduced.

A good deal has been written of late on lightning conductors, and not only does their original purpose seem to be overlooked, but they very frequently fail in their proper function, which is to tempt a silent discharge and not a "stroke." Indeed, they are said to act when they are struck, which itself is a proof that they are not doing their duty.

Franklin's suggestion in 1749 was "Would not these pointed rods probably draw the electrical fire silently out of a cloud before it came nigh enough to strike, and thereby secure us from the most sudden and terrible mischief?" I am informed there is a town in South Africa where every house is compelled by law to be provided with a lightning conductor, and that when a thunderstorm passes over it the numerous points fulfil their proper duty, and the whole of the discharge passes silently to earth; and that when the storm has passed beyond the protected region the lightning begins again.

Have any measurements of the current of a silent discharge been made? and is it known whether the discharge is continuous? Information is needed on these points before a thoroughly reliable lightning conductor can be designed.—Yours, &c, A. P. TROTTER.

LIGHTNING DISCHARGES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The explanation which Dr. Fleming has given of phenomena connected with lightning discharges cannot, I think, be considered very satisfactory. In order to explain the remarkable experiments brought before the Society of Arts Dr. Fleming throws out two suggestions, each of which is originally due to Dr. Lodge. The first is that the time of discharge is so short that the iron conductor has no time to be magnetised, and therefore possesses very little more self-induction than a copper rod of the same size. The second is that the greater specific resistance of the iron rod makes its time-constant less than that of the copper rod, and the discharge takes place more rapidly through the former in consequence. But the time-constant of discharge does not depend only on the self-induction and resistance of the rod. If the only advantage an iron rod possesses over a copper one is due to its greater resistance, it should be possible to improve it still further by giving the lightning conductor a bad earth. A flash of lightning is the sign of the discharge of a condenser formed by a cloud and the surface of the earth, the discharge circuit consisting partly of the lightning conductor, but chiefly of the air gap between the lightning conductor and the cloud.

Although Dr. Fleming has said a great deal about the resistance of the lightning conductor, he has entirely ignored the resistance of the air gap, and has said nothing about the capacity of the condenser. The two latter quantities have probably far more influence in determining the time of discharge than the other has. A lightning conductor has to discharge a given quantity of electricity quickly; it has nothing to do with the rapid establishment of a steady current. The potential to which the condenser is charged is so extremely high, that if it were maintained after the breaking down of the dielectric the current produced in the conductor would be enormous. A very small current for a very short time is, however, quite enough to discharge the condenser. It is therefore

Digitized by Google

only necessary to consider the initial rate at which the current rises, and this, although inversely proportional to the self-induction, is directly proportional to the E.M.F. producing the discharge. It does not depend in the least on the time-constant, and is quite independent of the resistance of the circuit. When the E.M.F. is practically infinite, as in the case of lightning discharges, the current rises to a small value instantly, whatever the self-induction may be. The influence of self-induction is, however, very important when the discharging current begins to fall. If there is no self-induction the current falls very rapidly, while if there is any the current is more or less maintained, according to the value of the time-constant. The condenser may in consequence discharge more rapidly when self-induction is present, because the average current discharging is larger. If the self-induction is very large the current may be maintained so long that it will discharge the condenser before it can fall to zero, and oscillatory discharges will result. This is perfectly illustrated by the analogy which Dr. Fleming has given. The inertia of the gas does not prevent the sudden rush from the first reservoir at high-pressure to the second one at low-pressure, but it does maintain the flow which results, and may produce oscillatory currents if the reservoirs are sufficiently small.

The time a condenser takes to discharge is actually diminished by inserting a moderate amount of self-induction into the circuit. This fact was first pointed out in a Paper I read before the Physical Society recently. It throws considerable doubt upon the general opinion that self-induction in a lightning conductor is a disadvantage. If the coefficient of self-induction L is less than $\frac{1}{2}$ K R^2, where K is the capacity of the condenser and R the resistance of the discharge circuit, the time of discharge will be less than if L were absolutely zero. If L is only $\frac{1}{4}$ K R^2, the time of discharge is halved. Now, if the resistance of the atmospheric circuit only consisted of the resistance of the lightning conductor itself, the product K R^2 would possibly be smaller than the coefficients of self-induction of ordinary lightning conductors. If, however, the resistance of the air gap is taken into account, this product may far exceed them, and, in the absence of experimental evidence, there seems to be no reason for believing that the insertion of a huge electromagnet into the circuit of a lightning discharge would be any disadvantage at all. Is it quite certain that lightning discharges are oscillatory in character? If they are so, it is not because the current is prevented from rising by the self-induction, but because it is prevented from falling. If they are not oscillatory, there seems every reason for believing that the self-induction could be more than doubled without causing the time of discharge to be greater than if there were no self-induction at all.

It may, I think, be questioned whether the important experiments of Dr. Lodge are really miniature representations of lightning discharges. The two outer coatings of his Leyden jars were connected, firstly, to the ends of the wire experimented upon, and, secondly, to the two knobs of a spark gauge. The ease with which the wire transmitted the discharge was estimated in terms of the corresponding distance between the knobs of the spark gauge. It seems reasonable to suppose that there should have been another air gap in the circuit to correspond with the air gap between the lightning conductor and the cloud. If the outside of one of the jars, instead of being directly connected with one terminal of the gauge and one end of the wire, were only connected to them by a large air gap, the arrangement would form a better representation of a lightning discharge.

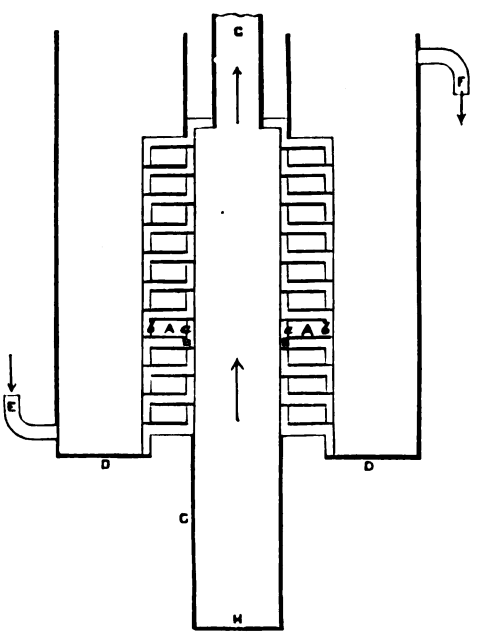
The problem is one which requires to be solved experimentally. If its solution is attempted mathematically, the portions of the solution which are not pure assumption are likely to be very vague. Dr. Fleming has objected on more than one occasion to the use of such "loose" expressions as instantaneous resistance; Mr. Oliver Heaviside has implied that such expressions are "utterly misleading." The word impedance, which has been used instead, has, however, no better claim to represent a physical quantity, and unless very carefully used is far more likely to be "utterly misleading." Resistance functions are very fine things when the coefficients of the different terms are constants, and where the quantities operated upon are simple sine functions. In such cases the word impedance can be exactly defined, and is very convenient to use. When, however, the coefficients of induction are functions of the current, and where the electromotive forces are no longer capable of being expressed in simple mathematical form, resistance operators are of little or no use, and the word "impedance" is one of very uncertain meaning. Dr. Fleming feels some of this difficulty when he considers the effect of magnetic lag, and invents the expression instantaneous impedance. If this means nothing more than the ratio of the electromotive force impressed on a conductor to the current flowing through it at the same moment, it is difficult to see what advantage (except a change of name) this phrase has over the corresponding phrase "instantaneous resistance," to which Dr. Fleming so much objects. If this is to be the definition of impedance, it will be necessary to abandon the one usually adopted; and if it is not to be the definition, it is hard to see whether the expression "instantaneous impedance" has any meaning at all.—Yours, &c. W. E. SUMPNER.

Central Institute, May 16th.

THERMOPILES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A description has recently appeared of a thermo battery constructed by E Raub, which is claimed to be something new. I may mention that I have made such a pile in



1885 at the machine shop of Mr. Ciriack in Bucharest, Roumania, which fact Mr. Ciriack can certify, as he aided me in the casting of the elements. The sketch herewith is taken from the original drawing which I handed to Mr. Ciriack at that time. I made a good many experiments then with thermopiles, and wanted to make a standard of E M.F., and in which I succeeded. After various shapes of elements I came upon the ring form, as the drawing shows. A represents one alloy or metal of an element, which was simply cast in the shape of a disc, while the other metal, B, takes the shape of a ⌐. At the points *a* and *b* each metal was well tinned with solder, and then both metals were well heated and joined together.

The insulation consisted of mica discs placed between them before they were joined together. I also made some that had threads cut, and screwed the elements upon each other.

At the bottom element was secured a tube, C, which was closed at its end, while another tube, G (open), was placed at the top of the pile. In this tube oil was poured, and then heated at the bottom H. Around the whole pile was a vessel, D, which had two opening taps at E and F. At the tap E

Digitized by Google

cold oil entered, and thus filled up the vessel, while at F it went out. Thus the cooling fluid could circulate. It will be seen that this form has one great advantage over others, inasmuch as the resistance is very low and the heating uniform.

It will also be seen that a good standard of E.M.F. could be obtained if the elements were made of pure metals, as the difference of temperature can be easily maintained. For practical purposes this form is very well adapted, as it is very compact, and large columns can be built which may receive their heated liquid from a boiler.—Yours, &c.,

Am Kiosk F, Brünn, May 11th, 1888. F. JEHL.

COMPANIES' MEETINGS.

West India and Panama Telegraph Company (Limited).

The twenty-second ordinary general meeting of the members of the above Company was held at Winchester House, 50, Old Broad-street, on Wednesday last under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the last general meeting, which were approved by the present meeting and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, the report and accounts refer to a half year which, considering that it is the poorer half of the two, has been the most successful we have had except one in 1883. Those who are old shareholders, no doubt, know that the sugar crop matures in the first six months of the year. That creates, in comparison with the second half, a certain amount of telegraphing business in connection with the crop, its out turn, shipment, &c.; therefore, the second half is not so successful in the way of revenue as the first half. They are both poor enough; and when I tell you that the gross revenue we receive per mile is not equal to one-half of the average gross revenue of other trans-ocean telegraph companies, it will be clear to you why I say that both half years are very poor. In the year 1883, with which I have been comparing our present condition, we had, as we have had in the last half year, certain windfalls. First we had an increase in the traffic over that of the corresponding period of 1882. In the next place we had done, as we have done in this half year—succeeded in chartering our ship. In the last half year we had the opportunity of chartering her to the International Ocean Telegraph Company for the repairs of their cable. On that operation there is a profit, and it also relieved us of the maintenance of the ship during the time she was engaged by the other company. This last half year the ship was away 29 days, which means a considerable relief in expenditure on the vessel. Besides these two circumstances there has been a profit on exchange. Generally, almost invariably, we lose in bringing our money home from the West Indies, but this half year we had a profit. Then there was a profit on the cable which we sold to the International Company for effecting the repairs for which our ship was chartered. We also had a saving of £250 on the debentures being issued at 5 per cent. instead of 6 per cent. Those conditions combine to enable us to pay 4s. a share on account of the arrears of dividend on the First Preference shares, besides the dividend on those shares; and in this respect we are in a very different position from what we were in 1883. In that year, in regard to the depreciation fund—a fund that is set aside to meet the depreciation that goes on every year in your plant—we were rather in the position in which the country now finds itself in the way of national defences, much behind, and instead of on that occasion giving an increased dividend on the First Preference shares, we felt it our duty to add the whole £15,000 that was over to the reserve fund. On the present occasion our reserve fund is in a much better position. After charging against it £7,000 odd, the value of the cable used in the further repair of the original Jamaica-Porto Rico section, and adding to it the contribution of £3,000 from the half year's revenue, our reserve fund for the depreciation of our cables is about level with the calculated depreciation for the year ended December 31 last. While I am speaking of the reserve fund it is satisfactory to point out that it is pretty nearly all invested in easily realisable securities, and that the market value of those securities is about £8 000 in excess of what they cost us. I am glad to be able to report the repair of the Jamaica-Porto Rico cable, which, however, has cost a great deal of money—£31,000 odd on cable alone, taking no account of the ships that have been employed for weeks and weeks in doing the work. It is a most important cable for us, because the greater part of our revenue-producing field, except Jamaica, lies east of Porto Rico; therefore, until we had repaired the cable between Jamaica and Porto Rico, we were dependent for the great bulk of our traffic on a single cable. Whatever, therefore, it cost us to repair was money well spent. I thought when our report was drawn out that we were going to have a meeting, for the first time in the history of the Company, with all our cables in order; but I am sorry to say that since the publication of the report there has been a break notified in the St. Vincent-Barbadoes cable. That is an important cable, because it connects two of our principal Colonies, and it has been several times interrupted lately. This question of the interruption of these two parts of our system that are not duplicated—that is the line between St. Vincent and Barbadoes, and the line between Trinidad and Demerara—brings me to another point. In both those Colonies they are moving for a duplication. I say, in reply, with a system that is not paying any revenue on three-fourths of its capital how can you, as commercial men, ask us, in view of the unfortunate terms that were originally assented to, to throw more money into the sea in order to make your communications more perfect? If we can obtain some modification in those conditions, I say that the Company will be ready to meet the Colonies fully half way, but until they do see their way to grant us some little concession I should myself feel very much indisposed to sink any more capital in so unremunerative an undertaking. I hope that that policy will have the support of the meeting. With reference to the accounts themselves, I do not think there is anything to necessitate my taking up your time; but I shall be very happy to answer any question. Before moving the resolution, I wish to refer briefly to the loss which I think we shall all feel in this room in the absence of a former very conspicuous member of our Company—a man who took a very important part on several occasions in our debates. I refer to the late Mr. William Abbott, who brought forward at our last meeting a very intelligent and clever measure for the re-arrangement of our capital. It was not my fate to meet Mr. Abbott anywhere except in connection with meetings of our Company, and I always found him a very able and fair man, and a fluent speaker. He did not always agree with me, but generally he took a very comprehensive view of our affairs. You know what has happened to his proposal. It was fully considered by us, and it was submitted to most able counsel—to Sir Horace Davey and Mr. Palmer—and it was found impossible to carry out. We asked Mr. Abbott to come and see us after we had obtained their opinion and he at once bowed to the superior views of legal authorities. The e the matter dropped. I can only say that I am very sorry we shall never see Mr. Abbott again among us. It is now my duty to propose:—

"*Resolved, that the Directors' report and accounts to 31st December, 1887, submitted to this meeting, be and the same are hereby received and adopted, and that, as recommended by the Board, a payment of 10s. per share on account of arrears of dividend on the First Preference shares be and the same is hereby declared.*"

Mr. WM. FORD: I have great pleasure in seconding that.

Mr. A. MORTEN said that the accounts of the half year scarcely gave a correct account of the value of the year's working, and with their permission he would lay that view of the case before them. The interest on the investments did not figure in the revenue account, where he maintained it ought to appear, amounting to £4,248, showing with the earnings from messages, subsidies, &c., £96,297. The entire expenses including interest on the debenture capital for the whole year amounted to £50,427, leaving a net revenue of £45,800 for the year. That would be sufficient to pay the First and Second Preference dividends in full, and there would be 5s. a share on the Ordinary shares. He challenged any one to controvert a single one of these figures, for they were perfectly correct. With respect to the scheme put forward by the late Mr. Abbott, he would not say there was any negligence, but something was overlooked by the Directors, probably in putting the case before Sir Horace Davey. He (the speaker) maintained that the Preference dividends had been earned for many years past, but that by the magnanimity of the shareholders the money had been put to reserve fund, and he held that it would be distinctly unfair to say that the interest had not been earned on those shares. The paucity of the attendance showed what little interest was taken in the affairs of the Company, and why was that? Because for eight or ten years the Second Preference and Ordinary shares had not received a penny. They had had the very life ground out of them by the treatment of the Directors. They were earning, as he had said, 5s. a share on the Ordinary shares, which were selling in the market at 2s. in the £; they had accumulated a reserve fund of £130,000, and the value of the securities was quite £10,000 in excess of that amount.

The CHAIRMAN: £8,000. We worked it out yesterday, and that is the result, taking the selling price of the securities.

Mr. MORTEN said that he also had made a calculation, and he repeated that the value of the investments was £10,000 in excess of the sum shown in the accounts. The whole of the arrears only amounted to £53,000, and he believed that any Board who took the question up with the view of settling it could do so in three months, and there would be no difficulty in getting a short Act of Parliament, which had been done in scores of other cases. If the arrears were paid off, the £10 shares would, he believed, be selling at £5 each instead of at the miserable 2s. in the £. He held 1,000 Ordinary shares and 180 Second Preference shares. Fortunately, he could afford to wait, but there were hundreds of poor shareholders throughout the country who could not afford to do so, and who when they required money were obliged to sell their shares and to make a severe sacrifice. He maintained that they were now in a state of prosperity, and that if the Board would only meet the shareholders' views the Company would rank as one of the commercial successes of London instead of one of the greatest failures ever seen. If the Company was so poor as seemed to be regarded, why did they pay 2,000 guineas a year for Directors' fees? If the Company were a bankrupt concern they ought not to pay such a sum. He was probably one of the largest shareholders in the Company, and he would never cease to speak at their meeting, as long as the present treatment of the Directors was continued. He concluded by moving the following resolution:—

"*That until the arrears of dividends on the First and Second Preferences have been paid off, no further sums be added to the reserve fund, and that the Directors be requested to confer with three of the largest shareholders as to the best course of paying off such arrears.*"

Mr. WM. FORD said that the motion was out of order.

The CHAIRMAN endorsed that statement, and said that no notice had been given of it.

Mr. MORTEN said that he knew enough of company law to know that he could move his proposal as an amendment, and he did so.

Mr. FIRTH, who said that he had paid £9 for his shares, thought there

Digitized by Google

was some strength in the suggestion that had been made that the reserve fund had now arrived at a sum where for a time it ought to be left. If the other half year should be like the past half year, there would be a net amount available for dividend of £40,000. The First and Second Preference dividends took £23,500, and there remained £17,000 a year practically if the present revenue continued for the purpose of paying off the remaining arrears on those shares, and then paying a dividend on the Ordinary shares. If that was a correct statement of the case the Company was certainly in a sound financial position. They only owed £53,000 for arrears, and if £17,000 a year was available for that purpose the arrears would be cleared off at the end of about three years. He asked the Chairman to state whether that was not so, and whether at the end of that three years there would not be £17,000 a year left, which was equivalent to 2 per cent. on the Ordinary shares. If that were so he thought they might look forward to the position of the Company with some satisfaction in the future. He felt that the Directors were doing the best they could for the shareholders.

Mr. ODELL said that he had been a shareholder in the Company for 16 years, and held 1,000 shares, for a large number of which he had paid £7 each. During those 16 years he had received about £20 in dividends. He asked whether it would not be possible to pay off the arrears out of their investments.

The CHAIRMAN: What is to become of the reserve fund in that case?

Mr. ODELL: We should then have a good reserve fund.

The CHAIRMAN asked whether it was right for a company using depreciating plant not to set aside out of its profits such a sum as was calculated to represent the depreciation that was going on in that plant. That was the real crux of the question. They had many cables, which had been down for seventeen years, and they went on depreciating. They could not specify exactly what the depreciation was, but they had taken a very liberal term for the life of their cables. That was one factor in their calculations. Another factor was the rate of interest they were likely to get on first-class securities; and the third factor was the cost of the cable to renew their system. With those three factors they made a calculation, and that calculation had given them almost within a shilling of what they had that day. But at the next half-year they would have again to add to the reserve fund, because another half-year's depreciation would have occurred in their plant. Was there any shipping company or any company using a wasting and depreciating plant which did not provide for depreciation every year? The fund was called a reserve fund, others called it a renewal fund, which was a better expression; but, as a matter of fact, it consisted of what ought to be written off before they ever began to talk of profits. He could not see his way to hold out any hope of the cessation of the depreciation fund. He did not think they wrote off too large an amount, and as he had said they took a very liberal view of the life of their cables. He might add that they had estimated to receive 3½ per cent. on their investments, but he doubted if they would be able to get 3½ per cent. on first-rate securities any more. That was a point which would seem to suggest a little increase to the reserve fund in order to meet depreciation.

Mr. MORTEN asked whether it was not the case that they had doubled nearly all their cables in the last few years out of revenue?

The CHAIRMAN said that that was not the case, and that the cables which had been duplicated were also depreciating.

Mr. JOHN GRIFFITHS (the auditor) stated that the Directors and the auditor were in a position of responsibility to the shareholders, and they were bound to make the reserves which they did. He regarded it as a personal responsibility. He looked with great care into the matter every half year, and he knew that the Directors most carefully watched it. The duplication of the cables to which Mr. Morten had referred as having been made out of revenue had been made out of capital. He was sure the reserve that was made for depreciation was only a fair and proper one.

Mr. MORTEN wanted to know out of what capital the cables had been duplicated if that work had been done out of capital.

The CHAIRMAN said that Preference capital had been raised for the purpose and Ordinary capital as well.

Mr. GUESDON: And debentures also.

Mr. GRIFFITHS stated that something like £500,000 in all had been raised for the duplication of the cables.

Mr. GUESDON regretted the attack that was made every year on the reserve fund, which he held it was indispensable for every company to have. He did not believe that they could have floated their debentures at 5 per cent. if they had not had a solid reserve fund, nor did he believe that they could have made a contract for their cable on the satisfactory conditions which he believed they had secured. He had heard nothing in respect of the Ordinary shares he had held for the last 15 years; but the position of an Ordinary shareholder was very well known. If the profits were very large he took them, but if they were not sufficiently large, and the business could not be carried on without pledging the property, the property was pledged in order to save the shareholders from being absolutely sacrificed. It was nonsense for the shareholders to complain of the reserve fund unless they could see that there was some unworthy motive on the part of the Directors in accumulating a fund out of proportion to the ascertained necessities of the Company. The life of the cables depended on their make, and also on the character of the ground on which they lay, and he believed that some of them lay in an unfavourable position.

The CHAIRMAN: Very unfavourable.

Mr. GUESDON, continuing, said that the Directors must provide for depreciation, or they would fail in the engagements which they had undertaken. He was unable to be present at the last meeting, but he regretted the moral obliquity which suggested that the arrears of dividend should be capitalised in order to promote the interests of the junior securities. He desired to know at what rate the ships were insured.

The SECRETARY: Six to seven guineas per cent.

Mr. GUESDON considered that that was a very high rate, and he suggested that the Board should calculate the whole sum which had been paid, not only by this Company but by other companies, for insurance, and see what the amount would come to as compound interest at 5 per cent.

The CHAIRMAN said that they had lately reduced the amount which they insured upon.

Mr. GRIFFITHS said that they had always taken into consideration the question of insurance and the amount set aside for the depreciation of ships.

Mr. GUESDON maintained that the reserve fund was a distinct fund, and that it had no right to be interfered with at all, and that everything which belonged to that fund ought to go to its credit. When, however, they had to renew a cable, it was quite legitimate to take money out of the fund.

The CHAIRMAN: That is what we do do.

Mr. GUESDON afterwards asked the Chairman to state what advantages the Company had derived from the late contract. He was pleased that they had departed from the principle of dealing with only one company, and in seeking for tenders, and he desired to know what benefit they had derived from that course.

The CHAIRMAN said that they had called for tenders, and they took the lowest one, but he did not think it would be fair to state the exact figures. They had taken the lowest tender, and as long as they were satisfied in regard to the question of quality that was what they would do.

Mr. GRIFFITH said that as a holder of Ordinary and Preference shares he sympathised with the arguments which had been adduced on both sides. He thought it was necessary for the interests of all classes of the proprietors that there should be a sufficient sum to enable them to have ready money in the event of any defect occurring in the cable. They must remember that the cables depreciated every year, and if the depreciation resulted in breakage there must be a reserve fund to come upon. He was not in favour of reducing the Directors' fees, but if he held as many Ordinary shares as some of the other speakers he would press the Directors to see that the greatest economy was observed in the working of the Company. With regard to the suggestion of Mr. Morten as to obtaining an Act of Parliament, he thought it should commend itself to consideration. He did not agree with Mr. Guesdon that the shareholders had no right to capitalise the amount of the arrears either on the First or Second Preference shares. If the Preference shareholders were willing to capitalise their arrears no injustice would be done to them, and a great benefit might be conferred upon the other classes of proprietors. At the last meeting he believed that the Directors were in favour of capitalising the arrears, according to the scheme brought forward by the late Mr. William Abbott. The only objection to it was that it could not be carried out by ordinary legal process, but there was nothing to prevent the Company from applying for an Act of Parliament.

Mr. GUESDON said that it ought not to go forth, as Mr. Griffith had argued, that there was a unanimous feeling at the last meeting in favour of capitalising arrears.

Mr. CUFF said he had always approved of the policy of building up a reserve fund.

Mr. HIBBERT said he had never attended a meeting where there had not been some discussion respecting the accumulation of arrears, and he thought it was a pity that the Directors did not try to adopt some middle course.

Mr. VEARS hoped that a limit would be put on the amount of the reserve fund. The Ordinary shareholders at present had to look upon themselves as benefactors to black people, sugar planters, and others; but they themselves were shut out from all the benefits of the working of the Company.

A SHAREHOLDER inquired what was the amount to which the reserve fund was to be increased. He thought that some Directors had reserve fund on the brain.

The CHAIRMAN: Broadly speaking, the reserve fund ought in the fulness of time to be such a figure as would enable us to practically relay your system.

A SHAREHOLDER: All the cables are not going to die at once.

The CHAIRMAN: But they will in time.

A SHAREHOLDER said that he believed the cables had exceeded the life which the Directors had anticipated for them.

The CHAIRMAN: We have given them a very liberal life in our calculations.

Mr. WILDING said that the reserve fund had been somewhat decreased during the half-year. He thoroughly objected to any "watering" of the capital.

The CHAIRMAN in reply said that Mr. Griffith was in error in believing that the proprietors were unanimously in favour of capitalising the arrears of dividend. With regard to the First Preference shareholders, the assents were 37·17, the dissents 12·91, and 49·92 did not reply at all. Of the Second Preference shareholders, 26·39 assented, 17·35 dissented, and no replies were received from 56·76. Of the Ordinary shareholders 58·82 assented, nearly 1 per cent. dissented, and 40·26 per cent. did not reply at all. When it was suggested that they should promote a Bill in Parliament, he must remind them that they must have the practical consent of the constituents, otherwise it was no use incurring expense. They had once before capitalised arrears, and the course taken on that occasion had given them a great deal of trouble. They did not pay income-tax on the reserve fund. The reserves on the ships were calculated on the balance of the cost after taking off previous reserves. The Chairman then proceeded to put the resolution.

Mr. MORTEN demanded that his amendment should be put first.

The CHAIRMAN: I have ruled that out of order. He then put the resolution in the usual way, and declared it carried by a majority.

A SHAREHOLDER asked whether the proposed cable from Halifax to Bermuda would affect the Company.

Digitized by Google

The CHAIRMAN replied in the negative.

Mr. GRIFFITH asked whether the shareholders might not expect as good a dividend for the current half year as they had had in the past half year.

Mr. FORD said that the traffic returns were published regularly.

The SECRETARY said that there had been a slight increase in the receipts compared with those for the corresponding period of last year.

On the motion of Mr. FORD, seconded by Sir JAMES ANDERSON, Mr. Earle was re-elected a Director of the Company, as was also Mr. Ford, on the motion of the CHAIRMAN, seconded by Mr. WM. ANDREWS.

Mr. CUFF proposed, and Mr. WILDING seconded, the reappointment of Mr. J. G. Griffiths as auditor of the Company, which was carried unanimously.

Mr. VEARS inquired whether the meeting could not authorise the Directors to convey to Mr. Abbott's widow some words of condolence.

The CHAIRMAN said that he had alluded with regret to the decease of Mr. Abbott in his opening remarks, and he thought that, without putting it into the form of a resolution, if a copy of what he had said were sent to Mrs. Abbott, it would have the same effect as the resolution.

Mr. HIBBERT then proposed, and Mr. WILDING seconded, a vote of thanks to the Chairman and Directors, which was unanimously agreed to.

The CHAIRMAN having briefly replied, the proceedings terminated.

Western and Brazilian Telegraph Company (Limited).

An extraordinary general meeting of this Company was held in the Great Hall of Winchester House, at noon on Tuesday, the 15th May, for the purpose of considering, and if thought fit, confirming the resolutions passed at the extraordinary general meeting of the Company held on the 26th April last, intended to modify the Articles of Association of the company, and to carry into effect the proposed arrangement with the London Platino-Brazilian Telegraph Company (Limited), referred to in the Directors' report submitted to that meeting. Mr. W. Andrews was in the chair.

The notice convening the meeting having been read by the Secretary.

Mr. W. PAYTON, the Chairman called upon him to read the minutes of the last extraordinary general meeting, which the Chairman signed.

The CHAIRMAN then said: Now the first resolution which I have to put to the meeting is the one altering the Articles of Association. It is, I am sure, quite unnecessary for me to trouble you with any remarks before doing so, as the matter was fully gone into at the last meeting. I beg therefore to propose that

"*The 6th and 7th Articles of Association, and so much of the 26th Article of Association as includes and follows the words 'but notwithstanding any rule of law or equity to the contrary, shall be cancelled.*"

This was seconded by Mr. WEAVER, and carried unanimously.

The CHAIRMAN: Resolution No. 2, which I now beg to move, is:—

"*That Article 50 shall be modified by expunging the words 'an ordinary meeting shall be held yearly,' and substituting the words: 'The ordinary general meetings of the Company shall be held half-yearly.'*"

Mr. WEAVER seconded this, which was put to the meeting and also carried unanimously.

The CHAIRMAN: That disposes of the alterations which it is proposed to make with regard to the Articles of Association. Before moving the next resolution respecting the agreement with the Platino Telegraph Company I am sorry to say that it is necessary to trouble you with the reading of it throughout. I know it has all been read before, but it seems that technically it is necessary that this meeting should hear it read before dealing with the resolution relating to it.

The agreement having been read, the Chairman said: Well, gentlemen, those who were present at the previous meeting have heard all that before, and as the whole matter was then fully discussed I am quite sure you do not wish me to trouble you with any further remarks on the subject. I therefore beg to propose the confirmation of resolution No. 3, viz.:—

"*That the agreement dated 18th April, 1888, between the Western and Brazilian Telegraph Company (Limited), of the one part, and the London Platino-Brazilian Telegraph Company (Limited), of the other part, be and the same is hereby approved and confirmed, and the Board are authorised to carry the same into effect.*"

Seconded by Mr. WEAVER.

Mr. PETO then addressed the meeting. He said: Mr. Chairman and gentlemen—I was not able to remain and see the result of the last extraordinary general meeting. I am not going to discuss terms in any shape or way, but I see by the report of that meeting that you were good enough to state to the shareholders that in consideration of the agreement being authorised, your Board were willing to give your services for five years gratuitously. Well, now, it does seem to me, and I have a substantial stake in the Company, besides representing a large number of shareholders, as Mr. Cunningham will tell you, that if, as we are given to understand, this agreement is so beneficial to this Company, it is most unreasonable for us to expect that these gentlemen are going to work for nothing; every labourer is worthy of his hire. Our Company is now in a very prosperous way, and we ought not to ask our Board to work for nothing. I recollect the day when the Western and Brazilian Telegraph Company was in very low water indeed. Your exertions have brought about the present state of prosperity, and I hope you will receive fair remuneration for your services. I do not know if it is necessary for me to move any resolution on the subject, but if it is I shall be very pleased to do so, and I am quite sure my friends here will support me.

The CHAIRMAN: It is very good of you to express your views with regard to the Board so kindly, but we have fully considered the question that was put before us as to our fees, and we were of opinion that it would be hardly consistent for us to suggest that you should compensate the Board of the other company for a period which embraces the future, if at the same time this Board, in working the undertaking for the future, should charge you. They thought you would be making under these circumstances a kind of double payment. That was the view we took—a view taken deliberately and after full consideration; and, so far as we are concerned, we have no desire to see any modification in reference to this matter. Of course the Board are entirely in the hand of the shareholders, but that was the *bonâ fide* intention of the Directors, and the same remarks, of course, apply to the other branch of the subject. I would therefore ask you to be good enough not to move the resolution you propose, but to allow me now to put the confirmation of the resolution I have just read to the meeting with respect to the agreement.

Mr. PETO: I may, I trust, ask this question, Do you wish to give your services? If so I, of course, have nothing further to say. I do not, however, think that the remuneration and compensation of the Platino directors has anything to do with the matter.

The CHAIRMAN: I am very pleased to hear these remarks, only, so far as we are concerned, we cannot interfere in the matter. We relegate it to the dim and distant future.

The Chairman then put the resolution, which was carried unanimously.

The CHAIRMAN: The next resolution which I have to put is—

"*That for the purpose of the said agreement and other the purposes of the Company, the capital of the Company shall be increased to £1,500,000 by the creation of 30,000 shares of £15 each, to rank pari passu with the existing ordinary shares of the Company.*"

Mr. WEAVER: I beg to second that.

The CHAIRMAN: It has been moved and seconded that this resolution shall be confirmed; those in favour please signify the same in the usual way. Carried unanimously.

The CHAIRMAN: The next and last resolution which I have to move is—

"*That the Directors may issue the shares required for the purposes and on the terms of the said agreement. The residue of the said shares may be issued by the Directors at such times, in such manner, and upon such terms as they determine.*"

This was also seconded by Mr. WEAVER, and carried unanimously.

The CHAIRMAN: Gentlemen, I beg to thank you for your attendance here to-day, and to say that the business of the meeting is now concluded.

London Platino-Brazilian Telegraph Company (Limited).

The tenth ordinary general meeting of the shareholders of the above Company was held at the offices of the Company, Winchester House, 50, Old Broad-street, on Tuesday last, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting and the minutes of the ninth ordinary general meeting held on May 23rd, 1887, as well as those of the extraordinary general meeting held on the 27th April last. These having been confirmed and signed by the Chairman as correct, the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: I have now to move—

"*That the report and accounts for the year ended March 31st, 1888, submitted to this meeting, be and they are hereby received and adopted, and that a dividend of 3s. per share be declared, payable this day, free of income-tax.*"

Before asking you to approve of this resolution I have a few remarks to make. Twelve months ago when I had the pleasure of addressing you I gave you a very full account of the Company's position and its progress. I stated at that time that negotiations were going on with the Brazilian Government and also with the Western and Brazilian Company with a view to their taking over the management of the affairs of this Company. As you are aware those negotiations are terminated, and meetings have been held confirming the resolutions arrived at. After I addressed you at the meeting the other day on the subject of the bargain we proposed to make with the Western and Brazilian Company, it was unanimously agreed by the shareholders that the management of this Company should be placed in their hands under certain conditions. Now, gentlemen, as those arrangements are likely to be carried out, probably this is the last meeting of the London Platino-Brazilian Company under the present directorship. I have no doubt they will hold their meetings as usual, and those who become interested in the Western and Brazilian Company, or who still continue with the London Platino-Brazilian Company, will have an opportunity of knowing how the new management succeeds. So far, I think I may say, without any hesitation, that when we took this Company into our hands, we took it in a very unsatisfactory state indeed. I think we leave it now in a thoroughly prosperous condition. We are going to pay you to-day, not it is true a very large dividend—probably you may say a small dividend—but we are leaving it in a progressive state. Our submarine cables during the year have earned considerably more than they did the previous year. At the same time, as I said the other day, the Western and Brazilian Company is equally progressive. It is a larger system altogether. This is a comparatively small one, and it ought to be worked more economically and quite as efficiently by the Western and Brazilian Company as it would be worked by the present

Digitized by Google

Board. Therefore, I repeat, we are now about to retire from the management of this Company and hand it over to the Western and Brazilian Company in a highly satisfactory condition. So far as figures show anything the change will be for the benefit of the London Platino-Brazilian Company, as I can say that the Western and Brazilian dividend is likely to be one per cent. more than that of this Company. I think this is a reason, gentlemen, which should satisfy you that the transfer is a wise one, and although it is with great regret that the Directors leave the position which they have occupied—a position in which they have received the very cordial support of the shareholders during the many years they have held it—at the same time I feel that, in the interests of telegraphy generally, which has become a large international system, the more we can contribute towards unity the more we shall contribute to the success of telegraphy all over the world. You may say that it is concentrating the control too much. But you must bear in mind that this leads to increased dividends, and the more we can bring the management into great centres the greater force will be given to it. Therefore, it is part of my policy—it has always been—in telegraphy, to bring it as much as possible under the control of a concentrated power, and a power which, whilst looking to the progress of the great work of telegraphy, also sees that it is done on sound commercial principles, so that the shareholders connected with it will be benefited alike with the great telegraphing public. I beg to move the resolution.

Mr. FRANCIS PAVY seconded the motion.

Mr. YOUNG supposed that the dividend warrants were not made up. If so he would like to move an amendment increasing the amount of the dividend, seeing that they were going to put £1,000 to the reserve fund, which he did not think absolutely necessary.

The CHAIRMAN replied that it was too late to move such an amendment. They must now look to the Western and Brazilian Company for increased dividends.

Mr. YOUNG expressed his satisfaction with the proposed scheme of amalgamation, against which, he said, he could see no possible argument.

The CHAIRMAN having given explanations of various points in the accounts raised by Mr. Cunningham and Mr. Fry, the resolution for the adoption of the report and accounts was passed unanimously.

On the motion of the CHAIRMAN, seconded by Mr. HOLLOCOMBE, the retiring Director, Mr. Francis Pavy, was unanimously re elected, as were also Messrs. Deloitte, Dever and Co., the auditors of the Company, on the motion of Mr. FORD, seconded by a SHAREHOLDER.

An extraordinary general meeting was afterwards held for the purpose of confirming a resolution approving an agreement dated 18th April, 1888, entered into by the Directors of the Company, with the Western and Brazilian Telegraph Company (Limited).

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said that he had explained so fully at the last meeting the nature of the agreement in question that he thought there was no necessity for opening up the subject further than to ask the shareholders for their approval of the resolution. He was very careful when he spoke at the last meeting to explain everything fully, and he said then that a one-sided bargain was not a good one. He always liked to make a bargain so as to be a little on the right side, and he thought he might say without fear of contradiction that they were a little on the right side by the scheme they proposed—not so much, however, as to make those who bought them in the slighest degree uncomfortable. In further reply to a shareholder, he added that the Board had taken legal advice, and were quite satisfied that they were doing the right thing. The resolution was as follows:—

"*That the resolution passed at the extraordinary general meeting of this Company, held on the 27th day of April last, such resolution being in the words following: 'Resolved that the provisional agreement, dated the 18th day of April, 1888, made between the Western and Brazilian Company (Limited) of the one part, and the London Platino-Brazilian Company (Limited) of the other part, be and is hereby approved, and that the Directors are hereby authorised to do all things necessary to carry the same into effect,' be and is hereby confirmed, so as to make the same a special resolution.*"

Mr. PAVY seconded the motion, which was carried unanimously.

The CHAIRMAN wished to be allowed to express his regret that this was the last time he was likely to preside at their annual meeting, but, at the same time, he desired to assure the shareholders that though their interests would be merged in the larger Company, he would consider it a matter of duty as well as of pleasure to follow the working of the Company under its new management.

Mr. YOUNG proposed a vote of thanks to the Chairman and the Directors, again expressing his belief in the wisdom of the amalgamation scheme.

Mr. CUNNINGHAM having seconded the motion, it was carried unanimously.

The CHAIRMAN briefly acknowledged the vote, and the proceedings terminated.

Woodhouse and Rawson (Limited).

An extraordinary general meeting of the shareholders in this Company was held at the City Terminus Hotel, on Wednesday, the 15th instant, under the presidency of Lieut.-General Sir John Stokes, K.C.B., R.E.

The SECRETARY (Mr. J. Shurmur) read the notice calling the meeting, which stated that the Board would thereat announce the interim dividend which it had been decided to declare, and explain the steps that it had been resolved to take in order to cope with the increasing business of the Company.

The CHAIRMAN: Ladies and gentlemen, it was competent to your Board to declare an interim dividend, and to make a further issue of shares without convening you in a general meeting, but the Board have considered it more fitting while making known to you the amount of interim dividend which they find themselves able to announce, to present you with a balance-sheet for your information, which will justify our decision and enable you to form an opinion on the position of the Company. We have much satisfaction in announcing that the first half-year's working has given a profit of over 40 per cent. per annum, but we do not propose to declare an interim dividend of more than 12 per cent. per annum on the amount paid up or credited as paid up on the several shares. We think it more prudent to carry the remainder—a sum of more than £3,000—to the current half-year, especially as it consists principally of shares in other companies which are growing in value, and which it is therefore better to retain than to sell now in order to declare a higher interim dividend. The Board have been fortunate enough to acquire since the formation of the Company some valuable patents at a merely nominal price, from which a very large return may very soon be expected; indeed, a license for one application alone in three different countries had been provisionally disposed of for over £4,000 and a royalty, a deposit having been paid for the same; but unfortunately the purchasers, for reasons quite independent of the patents, were unable to complete their arrangements, and forfeited the amount paid on deposit. As I have just now said, part of our profits consist of fully paid-up shares which we hold in the Universal Automatic Machines Company, partly in payment for patents that we sold to that Company, and partly in payments for work done for them. We instructed our auditor to value those shares, and to employ a professional man accustomed to valuations of the kind. He valued the shares at par, but we have only taken into account 85 per cent. of their par value, being the price at which a large number have lately changed hands. These shares were acquired shortly after the formation of the Company, and at the time the balance-sheet was taken, on the 31st December, 1887, they were only worth half their present value. At about that time we had offers for them at that price. We refused, however, to sell, believing that the shares would rise con-

siderably over par, and we preferred to borrow money from our bankers for increasing our business. It is well we have done so, for we have lately sold some of the shares at only 15 per cent. discount, and I hope before the end of the year to see their value very much enhanced. We therefore consider our valuation of them in the balance-sheet as fully warranted. As you see by the balance-sheet the actual amount of working capital put into the business on its being turned into a limited company was only £2,855. We considered it advisable on the formation of the Company to begin with a small capital, and show what we could do, gradually extending the business as we saw fit, the interest paid for advances from the bank being nominal compared with the profit made. As regards the increase of capital which we propose to make to further develop the business of the Company, I may mention that large contracts for lighting, the pushing of patents abroad, and the manufacture of plant at home, require us to lie out of our capital for considerable periods, and we have taken advances from the bank on account of our increasing business, though we make a large profit for giving such facilities. We have therefore come to a resolution to issue 6,000 ordinary shares, on which we only propose to call up the same amount as has been called up on the first issue—that is, 35s. per share by the 1st July, from which we shall derive £10,500, and £30,000 in Six per Cent. First Mortgage Debentures of £100 each, of which £15,000 will be paid up by the 1st of July, and the remainder by the end of the year. With this increased capital we confidently expect to show you even more brilliant results in the second year of our existence than in the first. The present shareholders have a prior right to the shares now to be issued, in the same proportion as they at present hold. We have much pleasure in announcing that very important negotiations which have extended over many months, and which will lead to a very great and lucrative extension of our business, have been brought to a satisfactory conclusion; but I cannot give you the details of this transaction, as there are heavy interests involved which cannot now be divulged. If any gentleman wishes to ask any questions we shall be very glad to answer any that may be put. After a pause he added: There is no further business to bring before you, and unless any one asks questions I shall consider the business terminated.

Mr. HAYES asked if the 14,100 shares, on which 35s. had been called up, represented the actual number that had been issued out of the 39,980, and whether it was to be inferred from that that all the shares were not taken up in the first instance.

The CHAIRMAN: Only 14,100 were placed at the disposal of the public. We thought we would not begin with a large capital. We reserved a certain number of shares to issue from time to time as we wanted the capital.

Mr. HAYES assumed, then, that what the shareholders were now asked to do was to confirm a further issue of original capital.

The CHAIRMAN: The Directors have full power to issue those shares without further confirmation, but they thought it would be pleasant to the shareholders to meet the Directors and to hear from them the state of the business. That was why we called you together.

Mr. HAYES: Before we part, may I ask if you declare the dividend?

The CHAIRMAN: Yes; I do declare it, at the rate of 12 per cent.

Mr. HAYES then proposed a vote of thanks to the Chairman for presiding, and said he regarded the statement which had been made by Sir John Stokes as very satisfactory.

Mr. PHILIP RAWSON seconded the motion, which was carried unanimously.

The CHAIRMAN briefly acknowledged the compliment, and the proceedings terminated.

NEW COMPANIES REGISTERED.

CITY OF MEXICO JUNCTION AND PACHUCA RAILWAY COMPANY (LIMITED).—On the 9th inst. this company was registered, with a capital of £570,000 in £20 shares, to construct and equip railways, tramways, telegraphs, telephones and other means of communication in Mexico. The subscribers are:—

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 523.—Vol. XXI. FRIDAY, MAY 25, 1888. Price 4d.

NOTES.

The *conversazione* of the Master and Wardens of the Honourable Company of Salters is not usually regarded as one of the leading events of the scientific year; but this year, at any rate, it will be remembered as affording one of the most interesting and valuable exhibitions of novel electrical appliances which has yet been given. This was chiefly due to the co-operation of Profs. Ayrton and Perry, who exhibited several new or improved instruments. There was, first, the new type of secohmmeter, which has now been reduced to a very practicable and convenient form, and which, as soon as standards of self-induction are ready, will be independent of a speed-counter. Next there was a Maxwell-Ayrton-and-Perry-Deprez-D'Arsonval galvanometer, which, for shortness, will be called a Maxwell galvanometer. This instrument combines the well-known practical advantages of the D'Arsonval type, with a remarkable freedom from the permanent magnet error which has hitherto militated against its use as a calibrated instrument. We anticipate that the small cost and great convenience of these instruments will lead to their very extensive employment for testing purposes. A full description both of this apparatus and of the new secohmmeter will be found further on. Lastly, we must find room to refer to the well-known "magnifying springs" of the same inventors, for which, by means of an ingenious combination, further uses have recently been found. We have always regarded this spring as the most remarkable and the most beautiful of the very numerous discoveries and inventions of Profs. Ayrton and Perry.

From a report in another column it will be seen that the Leamington Town Council are unable to come to a decision whether or not to give notice to terminate the contract with the local Electric Lighting Company. The one redeeming feature in this unhappy business—and even this has only a negative value—is to be found in the fact that the promoters are spending their own money and not that of other people. But, even so, it is impossible not to feel that either the extraordinary bad luck or the equally extraordinary bad judgment of the contractors has inflicted a very serious blow upon the prospects of electric lighting in the Midlands. The chances of undertaking central station lighting are not so plentiful in this country that we can afford to overlook a single failure. Those who embark upon such schemes would do well to realise that they will certainly be held "morally responsible" to the whole profession for the success of their undertaking. Electrical engineers, however much they may disagree amongst themselves, have nevertheless too much good sense not to know that their interests are far better served by the success than by the failure of every central station that has been or will be started in this country for some years to come, no matter what system may be employed. We feel sure that the failure, or, if that be too harsh a word, the incomplete success, of the Leamington installation has been a source of sincere regret to all electrical engineers and contractors. But, on the other hand, however much we may sympathise with Messrs. Chamberlain and Hookham, it is very difficult indeed to understand why a tolerably simple and straightforward undertaking, such as the distribution of a few hundred lamps on a three-wire system of mains, can ever have been allowed to fall into so lamentable a condition. We think it only due to the profession, which has sustained involuntary injury at their hands, that Messrs. Chamberlain and Hookham should, at the proper time, make public the history of the whole affair. If there be any mysterious and hitherto unsuspected difficulties in the three-wire system, certainly the sooner we know them the better.

Meanwhile we shall only now refer to one point of detail. In our own opinion a great mistake was made when it was first decided to use 16 candle-power incandescent lamps for street lighting at Leamington. No doubt a 16 candle-power lamp is as good as an ordinary street gas flame; but then the public expects from the electric light something a great deal better. If arc lamps are objected to, then we believe it to be bad policy to employ anything less than about 100 candle-power incandescents for street lighting. At Leamington we understand that it is proposed to remedy matters by replacing twenty lamps of 16 candle-power by ten of 32 candle-power. This seems mere trifling. We are also sorry to see that Mr. F. Joel is going to light the streets of Barnet with low candle-power incandescents. It appears to us that Mr. Joel will have a good many difficulties to overcome at Barnet, and we think it a pity that he should handicap himself with a scheme of street lighting which can scarcely fail to prove unpopular.

The "Mordey Alternator," which we describe in another column, is not only a strikingly novel, but also a highly successful machine, electrically, mechanically, and economically. In the case of a design involving so wide a departure from conventional types it is also worthy of note that the first

Digitized by Google

machine, built without previous experiment of any kind, yielded results within a very small percentage of Mr. MORDEY'S calculations. The Anglo-American Brush Corporation may now be congratulated on having completed their equipment for dealing with alternating current distribution.

A CORRESPONDENT, whose letter will be found in another column, calls attention to the fact that in our issue of December 16, 1887, we reprinted from the *Journal* of the Franklin Institute a paper by Prof. E. J. HOUSTON describing the Tavener coulomb meter, which was patented in this country in the year 1884. This meter consists of a double-bulbed glass tube, like a differential thermometer. The tube is poised at its centre of gravity, and each bulb contains a wire spiral. The current being passed through the wire in one bulb expands the air, which drives a mercury column into the other bulb. This, now being weighted, descends and closes a switch, which sends the current through the opposite bulb. An alternate see-saw motion is thus produced, which is measured by suitable counting apparatus. Now, in our American letter dated April 28th, and which appeared on page 26 of the present volume, Prof. ELIHU THOMSON is credited with the invention of what certainly appears, on the face of it, to be an instrument "substantially as described" by Mr. TAVENER. It seems to us highly probable that a perfectly successful meter, suitable for continuous or alternating currents, can be made on these lines, and we shall be glad to have the question of priority of invention settled at its earliest stage. No doubt Prof. THOMSON can explain the circumstances under which he patents an invention recently ascribed by his own colleague to some one else.

THE "ten minutes" rule announced at the last meeting of the SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS will be recognised as a well-meant effort on the part of the Council to meet a growing difficulty. The difficulty has arisen both from its growth in numbers and the increased interest in the proceedings of the Society, and it is not an easy one to deal with. We are unable to feel quite confident that the experiment which is now to be tried will prove entirely successful. It is not that we think the rule too stringent; what is to be feared is that the younger and more modest Associates or Members, dreading to listen to the tones of the warning bell, and still less prepared to face an appeal to the mercies of the audience, will content themselves with a scant five minutes or relapse into silence altogether. A far more convenient, more effectual, and certainly more dignified course, would have been to leave the matter absolutely in the hands of the Chairman, who each evening could be guided as to what limit of time he should fix for the speakers by the character of the Paper that has been read and the amount of discussion it is likely to provoke.

THERE is another subject of even greater importance which, we trust, will speedily engage the attention of the Council. The status of the Society as a Scientific Institution has not yet become a matter of unconcern to the majority of the Members, however much the action of certain individuals might be held to prove the contrary; and that status is not, unfortunately, so high at present that the Members—especially Members of the Council—can afford to neglect the *lex non scripta* which should govern the proceedings of an assembly having pretensions to the position of a scientific body. It is no doubt a healthy sign that a very strong feeling has been roused on the subject, and we trust that sufficient has been said to prevent the examp'e from being followed up. If not, then, when we next have a Paper on the Leclanché cell we shall expect the author to tell us that he will be happy to supply them at so much a gross, with 12½ per cent. off for prompt cash.

THE problem of the alternate-current motor continues to receive a great deal of persistent and not altogether unsuccessful investigation. From our knowledge of experiments in progress in more than one quarter, we had hoped that the first thoroughly practical solution would be announced from London. But if this is to be the case our friends ought apparently to lose no time in completing their experiments. In another column will be found an account of a highly interesting and ingenious device of Prof. FERRARIS, who, by means of the combination of two alternating fields displaced by a quarter-phase, obtains the practical equivalent of a rotating field. That the device will readily lend itself to the construction of an alternate-current meter is almost certain, but whether it will make a practicable motor it is as yet too early to speak with confidence. There can be little doubt, we think, as to the absolute novelty of the idea, so far as regards previous publication; and yet we hear this week from America of a device, which, so far as our information at present goes, seems to bear a good deal of similarity. This latter invention is due to Mr. NIKOLA TESLA, and he was to have read a paper on the subject before the American Institute of Electrical Engineers on the 16th of the present month. One of the Transatlantic journals has already published an article based evidently upon the patent specification, but we must confess that we are unable to make head or tail of the details.

THE French technical journals are full of lamentation and sorrow. The obnoxious and absurd electric lighting regulations imposed twelve months ago have been re-issued and confirmed by the Prefect of Police, and their authority has now been extended by the endorsement of the "Conseil d'Hygiène," the "Commission Technique," and the "Commission Supérieure des Théâtres." We published the full text of these regulations in our issue of March 25, 1887, p. 446, and as the alterations seem to be unimportant it will scarcely be worth while to reprint them. While many of the provisions are, as may be supposed, such as will commend themselves to the English electrician, there are some others which cannot be read without a feeling of impatience, and to which the description above applied to them will not seem one whit too strong. Such, for instance, are the rules which require that the chimney shaft of all boilers used for electric lighting must be carried to a height of 15ft. above that of any other chimney within a radius of 650ft.; that if batteries are used a special air shaft must be built for ventilation, and must open above the roof; that the maximum

Digitized by Google

difference of potential with alternating currents must not exceed 120 volts. This last is of course a fatal blow to transformers in Paris. It seems as if London may even now escape from the ignominious position on the list of capital cities lit by electricity which it has hitherto seemed likely to occupy.

AMONGST the heterogeneous multitude of crude, worthless, or exploded ideas for which "Her Majesty's Letters Patent" are solemnly issued year by year—a farce from which, indeed, no inconsiderable portion of the revenue of the Patent Office is derived—many of our readers will no doubt recognise an old acquaintance in the description of an electro-magnet, which is built up of concentric iron tubes alternating with coils of copper wire. It is scarcely necessary to remark that, since each sheath more or less magnetically short-circuits the one next within, such a design is only advantageous if it be required to construct a bar magnet having the maximum weight of material with the minimum external field. This is not exactly the condition required for the field-magnet of a dynamo; yet it is for dynamo machines that the "inventor" usually considers his design chiefly valuable. This, for instance, is the idea entertained by the latest patentee of the "compound magnet." We refer to the specification filed by Mr. H. WATT, No. 9,853, dated July 13th, 1887. Surely this is not the secret of the famous Watt dynamo, upon which the shareholders of the MAXIM-WESTON COMPANY have learnt to place their hopes?

THERE was a severe thunderstorm in Glasgow last week, and a local journal seizes the occasion to instruct the ignorant multitude upon the relation between the electric light and lightning. We quote the following from the *Glasgow Evening News*:—"There is no danger whatever. The current from the time it leaves the motor is protected by strongly insulated wires, and lightning, therefore, cannot touch it there. Should the natural electric fluid find its way to the dynamos it might cause the light to flare up momentarily, but that is all. The current which drives the lights is quite strong enough to absorb the lightning." From the same journal we learn with considerable interest that a display of globular lightning was witnessed in the city during the same storm. This sapient scribe, however, knows far better than to believe in "the palpable absurdity of such stories," and proceeds in the approved style of the penny-a-liner to show his own total ignorance of a well-established phenomenon. We should be very glad to have further information as to this alleged appearance of globular lightning on the 19th inst.

Weston-super-Mare.—The Weston-super-Mare Town Commissioners have at length instructed the Finance Committee to report upon a proposal for the adoption of the electric light. The cost is estimated at £20 per lamp per annum, equal to a rate of 1d. in the pound.

Electric Light v. Gas.—General Festing, in a report to the Science and Art Department of the Privy Council, says the working expenses in connection with the lighting by electricity of South Kensington Museum amounted to £1,224. If the same portions had been lighted by gas the cost would have been £2,845. There was thus a saving of £1,621, which is 50 per cent. on the cost of machinery and apparatus.

Berlin.—According to the *Elektrotechnische Zeitschrift* the Anglo-American Brush Corporation has submitted a contract for lighting some of the streets of the town to the municipal authorities of Berlin. The contract is for 150 arc lamps and four 40-light dynamos. There are to be four separate underground circuits, the lamps are to be run, one half all night and one half up to midnight; the charge is to be 3½d. per lamp-hour, and it is estimated that there will be 400,000 lamp-hours per annum.

The House-to-House Electric Light Supply Co. (Limited).—We are informed that the directors of this company have ordered for their Central Lighting Station at West Brompton the following plant:—Three horizontal coupled compound steam engines, from Messrs. John Fowler and Co.; three water-tube steam boilers, with heaters and feed pumps, from the Babcock and Wilcox Company; and three sets of alternating-current dynamo-electric machinery, from Messrs. Elwell-Parker (Limited), of Wolverhampton.

Barnet.—The Barnet Local Board have affixed their seal to a contract for the lighting of their town by electricity, the contractor being Mr. Henry Francis Joel. The price which the Board formerly paid for gas supplied to the public lamps was 4s. 6d. per 1,000 cubic feet. Since the commencement of the negotiations with Mr. Joel the price has been reduced to 4s. 3d. The contractor undertakes to light the streets by electricity by August 29th, to use underground wires, and to make a charge based on 4s. per 1,000 cubic feet for gas. He also offers to supply private consumers at a similar rate, or, if they prefer it, at a charge of £2 per light per annum. The Board have had their choice of arc or incandescent lights, and have decided to have the latter. The contract is for three years.

Kensington Vestry.—At a recent meeting of this Vestry, Mr. Tisdall moved that the Town Hall be lighted by electricity, and that the Special Purposes Committee be requested to advise the Vestry as to the tenders referred to in their report (dated April 24th) for running mains and wires for supplying electricity to light the Town Hall and offices, and for the supply of the necessary fittings.—Mr. Braye moved as an amendment that the matter be deferred one year.—On Mr. Braye's amendment being put 25 voted it, and for Mr. Tisdall's motion 27.—Mr. Braye called for a division, which resulted in 27 voting for his and 30 for Mr. Tisdall's motion.—Mr. Moss moved a further amendment on the first motion, "That the matter be deferred for three months."—Mr. Broom seconded.—This was carried by 33 to 20.

American Institute of Electrical Engineers.—The annual meeting of this Institute was announced to be held in New York, on Tuesday and Wednesday, May 15 and 16. The following Papers were to have been read:—"On a New System of Alternate-Current Motors and Transformers," by Mr. Nikola Tesla; "The Possibilities and Limitations of Chemical Generators of Electricity," by Mr. Francis B. Crocker; "Underground Electrical Systems in Europe and America," by Prof. G. W. Plympton, of the Brooklyn Subway Board; "On Compensated Resistance Standards," and "On Prof. Moler's 'Swinging Arm' Galvanometer," by Prof. Edward L. Nichols, of Cornell University; "The Patent Court and Uniformity in Patent Practice," by Mr. George H. Stockbridge; "Protection of the Human Body from Dangerous Currents," by Mr. P. B. Delany.

Paris Exhibition, 1889.—The executive council of the British section announce that they are prepared to receive

Digitized by Google

applications from intending exhibitors up to the 9th of next month, at which date it will be absolutely necessary to commence the allotment of space. It appears that very little, if any, more space can be given to this country, which already has a large proportion of the amount allotted to foreigners, the demands made by native exhibitors having been unexpectedly large. As regards the industrial departments, it is now certain that an excellent representative display will be provided; some of the classes are practically filled up, though in others there is still room available for allotment. Nearly all the outside space available has been disposed of, so that any exhibitors wishing to show in the open air, or to erect small pavilions for themselves, must apply at once, and it is even now doubtful whether any more can be accommodated.

Earth Connections for Lightning Conductors.—The German electrician and his friends, the gas and water engineers, appear at present to be much exercised in their minds as to the advisability of lightning conductors being in metallic connection with the gas and water pipes. Opinions, it would appear, differ very much on the subject; one gentleman apparently thinking that if they were so joined the lightning might get from a house to the water mains and thence find its way into other houses in the neighbourhood. The general consensus of opinion, however, seemed to be that they should be in connection, but that the conductor must, in addition, have a thoroughly good independent earth-plate, as, failing this, the connection would be a source of danger. Should any of our readers wish for further information on this subject they will find a Paper by Prof. W. Kohlrausch in the *Elect. Tech. Zeits.* for May, and a long discussion in the *Centralblatt*, No. 12.

Electricity in the Navy.—The Engine Room Telegraph Committee, which have been sitting at Portsmouth for more than a year, have now prepared their report. As a consequence of their experiments and deliberations it has been determined to fit the whole of the ships of the Admiral class with electric, in addition to the usual mechanical, telegraphs for communicating between the bridge and the engine room. As the ventilation of the dynamo flats in these ships is so bad that it is well nigh impossible for the men to live in them for any length of time, it has also been resolved to provide them with peace fittings in the shape of additional dynamos. These will be placed on the main deck, and will be of 100 ampere power. In time of war the service dynamos, which are below the water-line, and are protected from shot, will be used for the search lights and glow lamps. Another innovation is to be introduced, whereby four projectors will be fixed in each of the "Nordenfelt" projections at the corners of the superstructure deck, so that in case of an expected torpedo attack the ships will be able to surround themselves with radial beams of light.

Bournemouth.—At a meeting of the Bournemouth Improvement Commissioners held on Tuesday morning, under the presidency of Mr. W. Fisher, the committee of the whole board reported the receipt of a draft licence under the Electric Lighting Act, 1882, and that after considerable discussion as to the application of Messrs. Phillips, Harrison and Hart for sanction to their application to the Board of Trade for a licence to supply electricity for public or private purposes within the district, it was resolved at a meeting of the committee held on the 8th inst, "That this committee recommend the Board not to give their sanction to the application at present."—The Chairman said the committee did not feel disposed that the Board should give any monopoly in this matter.—Mr. Hankinson said he thought that if they refused this application they would have to refuse to accede to other applications.—Mr. Cutler said he thought that the electric light had not yet arrived at such a state of efficiency as would warrant the commissioners in giving their support to any particular company, and so handing themselves over to a monopoly such as the gas and water company.—Mr. Ridley said he also felt that it would be unwise for them to tie their hands to any company to the exclusion of any other better system. He understood that at Leamington the electric light had not been a success, and that a member of the council had given notice that at the next meeting he would move that the contract for the electric light should be rescinded, and that they should "go back to gas."—Mr. Rebbeck said he thought that if any company was started at Bournemouth it should be under the control of the local authorities.—The recommendation of the committee was agreed to.

Bath.—At a meeting of the Bath Town Council on Tuesday, the recently appointed Electric Lighting Committee brought up their report, and the Chairman (Mr. Sturges) moved:—"That the Council instruct the Committee to obtain tenders for lighting a central area by electricity." He said he had ascertained from Mr. Massingham that the probable cost would be half as much again as they were at present paying for gas lighting. Several of the leading citizens were willing if necessary to form a local company for supplying the light at the lowest cost of production. Mr. Radway seconded. Mr. Cox moved an amendment to add to the resolution the following clause:—"And that the Committee invite the Gas Company to tender for supplying a better light than they did at present." Alderman Clark seconded. Several members thought that if the Gas Company would supply gas of 30 candle-power, it would be as great an advantage to the citizens as the introduction of the electric light. Major-General Burn said he should be very sorry to find the question of gas introduced into the resolution, for not only did he look upon the electric light as a much better illuminant than gas, but also as being much safer for the city. If they had their streets lit with it, they would get it introduced into the theatre, hospital, and other public buildings. Several members thought that even if the Gas Company could be induced to raise the illuminating standard of the gas supply to 30 candle-power, it would still be unable to compete with electricity, and fail to satisfy the requirements of the citizens. On the amendment being put, only six voted for it. The resolution to advertise for tenders for electric lighting was then put and carried unanimously.

The Electric Lighting of the Birmingham Library.—In our last issue we quoted a paragraph from the Birmingham *Daily Post*, stating that a scheme had been set on foot for the establishment of a central lighting station at Birmingham, in connection with an installation for lighting the public library. From a letter which has since appeared in the same paper we gather that the paragraph was of a somewhat misleading character. We therefore subjoin the letter in question, as follows:—"Sir: I notice in to day's issue of your paper [the *Daily Post*] a paragraph under the above title, in which you state that the committee had consulted Messrs. Chamberlain and Hookham as to the practicability of lighting the library by electricity. From this it would appear that the question had only recently been considered by the committee, but as a matter of fact it had been under their careful consideration for the past two years. It is only fair to state that at least eighteen months ago the committee consulted Mr. Henry Lea (of the firm of Henry Lea and Thornbery, consulting engineers),

Digitized by Google

one of the proprietors of the library, who in a report dated January 24, 1887, clearly showed that the library could very conveniently be lighted by electricity at a moderate cost. Mr. Henry Lea gave a considerable amount of time and attention to the subject, and the committee are indebted to him for the very valuable information they received. Messrs. Chamberlain and Hookham have recently been consulted on another side of the question—the renting of plant, or the purchase of light by meter. The question is still under consideration, but the committee have not yet determined whether or not to adopt any system of electric lighting.—JOHN ANTHONY, M.D., president of the Birmingham Library, Greenfield-crescent, Edgbaston."

Thunderstorms in the North.—A severe thunderstorm broke over Glasgow and the neighbourhood on Saturday last, with fatal results. The following is *The Times* account:—At about a quarter to 5 o'clock three boys were walking across the green, when a vivid flash of lightning struck down two of them. The bodies were at once taken to the Eastern police office, where they were examined by a medical gentleman. The names of the boys are Charles M'Dougall and William M'Lederas, both residing in the East End. M'Lederas' hair was singed and his head and chest badly scorched. Externally the only injury that M'Dougall appeared to have was a black mark round his throat. The ground where the boys were killed was very much torn up by the lightning. A later account states that the three boys were sitting in a row on the grass, and that the boy in the middle escaped injury, his companions on either side of him being killed. W. Sharp, a joiner, residing in Govan, and a man whose name is believed to be George Ingram, engineer, of Cromwell's Plantation, were found lying on the Paisley road, near the Halfway House, between 4 and 5 o'clock. On being conveyed to the Govan police office they were examinied by Dr. Barrie, who found that Ingram had been killed and that Sharp was suffering from severe nervous shock, but that he was not likely to be the worse for the accident. There was a hole in the felt hat worn by Ingram, evidently made by the lightning. A horse in a stable at Govan was also killed by the storm.—A violent thunderstorm broke over the village of Allonby, Cumberland, on Saturday afternoon. Three houses on the sea shore were struck by lightning. The fluid passed down one of the chimneys of each of the three houses. The furniture was smashed to pieces. An almanac hanging in a kitchen was torn into shreds, the paper was stripped from the walls, the glass of a picture was shattered nto fragments, leaving the picture itself uninjured, plaster was torn from the walls, and plates were thrown off a dresser. The gilding of a picture frame hanging in another of the houses was taken off as though it had been scraped away. Mrs. Carruthers, who was standing in one of the porches, had a very narrow escape. The lightning knocked her down and rendered her insensible. She soon recovered, however, and is not seriously injured.—A violent thunderstorm broke over Dumfriesshire on Saturday. At Closeburn, about twelve miles from Dumfries, a man who was driving a pair of horses in a field was struck by lightning and instantly killed. The horses were also killed. Many large trees have been torn up by the roots, and much damage is reported from various parts of the district.

Leamington Central Station.—At a meeting of the Leamington Town Council held last week, the Mayor (Mr. J. Fill) presiding, Mr. Crowther Davies moved, "That the Town Clerk be instructed to give forthwith, on behalf of the Corporation, twelve months' notice, under clause 4 of the agreement dated the 10th day of August, 1887, and made between the Midland Electric Light and Power Company (Limited) of the one part, and the Mayor, Aldermen, and Burgesses of the Borough of Royal Leamington Spa, of the other part, to determine the supply of the electric light." He had named twelve months' notice, because that was the only notice that could be given under the agreement with the company, and he did not object to it, because that would allow the company ample time to make any experiment they liked, and if they could bring the electric light to a satisfactory position he would be willing to let the motion lapse; but he did not think they would be able to do anything of the kind. The present state of the lighting by electricity was not so good as the former system of lighting by gas, nor was it so cheap. On the 2nd of May there were not fewer than eleven electric lamps out, and that was not an exceptional state of things. While desiring to be just and generous to the Midland Electric Light and Power Company, he could not but conclude that they had made a mistake, and that they never would be able to make the light satisfactory.—Mr. Herbert Stanley seconded the motion, which he believed to be in accord with the public wish.—Mr. Harvey said the light was not satisfactory even to the residents in the parade. It was a good light for shops, but in the streets it was not sufficiently diffusive, and in his opinion the lights were not more than eight candle power, although they were to be sixteen candle-power.—Mr. Barter White said the glowing promises of the promoters in this matter had not been fulfilled, although the cost of the new light was 100 per cent. more than the gas.—Dr. Thursfield said he thought that the Council had acted unwisely in removing their old gas lamps, which he believed they would have to put up again. He sympathised with the company, because they had been experimenting with their own money; but still he regarded the electric light as a dismal failure. Still he would not support the motion, as he should like the company to have an opportunity of offering the town something better than they had at present.—Mr. Waring announced that he looked upon the electric light as a failure, and should vote against it.—Mr. Salmon said he was not satisfied with the light, but he could not endorse all that had been said against it. In his opinion, it was neither a success nor a failure in the extreme sense in which the terms were used. He could not vote for the motion that day, but if the light continued as at present, at some not very distant period such a notice would have to be given.—Mr. Orton said one could not go down the parade at night without finding from ten to a dozen lights out, and on one occasion he counted twenty-six lights that had gone out between Bath-street Bridge and the Town Hall.—Mr. Alderman Wackrill contended that the present system of electric lighting was better than the old system, but still it was not what he wished to see it, and therefore he thought the company should have a further opportunity of improving the supply.—Mr. Overell said he was not holding a brief for the Midland Electric Light and Power Company, but he wished them to have fair play. In his opinion they had not had a full opportunity, and as a resolution like this would prejudicially affect the interests of the company, he thought it ought not to be passed without a further trial.—Mr. Purser took a similar view, especially as the company had spent nearly £30,000 in supplying plant for the electric light.—The Mayor said he considered the system had been a success. The resolution, if carried, would send the Electric Light Company out of the town. After the company had spent so much money, it would be most unfair to them to carry such a resolution.—On the vote being taken there were 10 in its favour and 10 against it.—The Mayor refused to give a casting vote.

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(*Continued from page 736, Vol. XX.*)

Lord Rayleigh has treated the problem of the impedance of branched circuits under the assumption that any number of circuits are connected in parallel, possessing each self-induction, but having no mutual induction.*

The problem is: given the resistance and induction of each branch, to find the compound resistance and inductance, or equivalent resistance and inductance of the system, for simple periodic currents of given frequency.

Let R and L be the resistance and inductance of any branch, and p the pulsation $= 2\pi n$. Let R′ and L′ be the compound or equivalent resistance and inductance of the system of parallel conductors.

The solution of the problem given, for which we refer the reader to the original paper, is

$$R' = \frac{A}{A^2 + p^2 B^2} \text{ and } L' = \frac{B}{A^2 + p^2 B^2},$$

where $$A = \Sigma\left(\frac{R}{R^2 + p^2 L^2}\right)$$

and $$B = \Sigma\left(\frac{L}{R^2 + p^2 L^2}\right)$$

If we take, as usual, $\tan\theta = \frac{pL}{R}$, and write $(I\,m)$ for impedance, where $(I\,m)^2 = R^2 + p^2 L^2$, we can write the above relations

$$A = \Sigma\frac{R}{(I\,m)^2}$$

$$B = \Sigma\frac{L}{(I\,m)^2}.$$

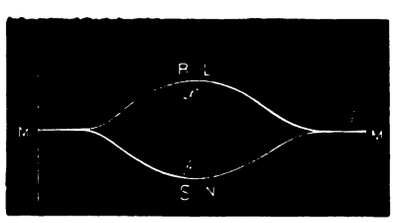

FIG. 33.

Let $R'^2 + p^2 L'^2$ be written $(I\,M)^2$. This is the compound or equivalent impedance of the system of parallel conductors. It is obvious that

$$(I\,M)^2 = R'^2 + p^2 L'^2 = \frac{1}{A^2 + p^2 B^2},$$

when $$A = \Sigma\frac{R}{I\,m^2} \text{ and } B = \Sigma\frac{L}{I\,m^2};$$

hence $$(I\,M)^2 = \frac{1}{\left(\Sigma\frac{R}{(I\,m)^2}\right)^2 + \left(\Sigma\frac{L}{(I\,m)^2}\right)^2}.$$

Consider the case of a pair of conductors in parallel (Fig. 38), having resistances R and S and inductances L and N, but no mutual inductance.

Let $$\sqrt{R^2 + p^2 L^2} = I\,m_1, \text{ and}$$

$$\sqrt{S^2 + p^2 N^2} = I\,m_2, \text{ and}$$

$$\sqrt{R'^2 + p^2 L'^2} = I\,M;$$

then $$I\,M^2 = \frac{1}{\left(\frac{R}{I\,m_1^2} + \frac{S}{I\,m_2^2}\right)^2 + \left(\frac{pL}{I\,m_1^2} + \frac{pN}{I\,m_2^2}\right)^2};$$

or $$I\,M = \frac{I\,m_1\,I\,m_2}{\sqrt{I\,m_1^2 + I\,m_2^2 + 2(R\,S + p^2 L\,N)}};$$

or $$I\,M = \frac{\sqrt{R^2 + p^2 L^2}\ \sqrt{S^2 + p^2 N^2}}{\sqrt{(R+S)^2 + p^2 (L+N)^2}}.$$

The lag ϵ of the main current just before branching, considered with respect to the impressed electromotive force, will be given by the equation

$$\tan\epsilon = \frac{pL'}{R'};$$

hence $$\tan\epsilon = \frac{pB}{A} = \frac{\Sigma\frac{pL}{I\,m}}{\Sigma\frac{R}{I\,m}}$$

generally, and in the case considered will be

$$\tan\epsilon = \frac{\frac{pL}{R^2 + p^2 L^2} + \frac{pN}{S^2 + p^2 N^2}}{\frac{R}{R^2 + p^2 L^2} + \frac{S}{S^2 + p^2 N^2}};$$

hence after reduction

$$\tan\epsilon = \frac{(S^2 + p^2 N^2)\,pL + (R^2 + p^2 L^2)\,pN}{(S^2 + p^2 N^2)\,R + (R^2 + p^2 L^2)\,S}.$$

This is the equation which determines the *lag of phase* of the current i behind the impressed electromotive force in the main branch before dividing into the branch currents x and y in R and S respectively.

Compare this equation with that which determines the angle by which the phase of the branch current y in S is *ahead* of the main current i. It is, as we have seen,

$$\tan\theta = \frac{(SL - RN)\,p}{R(R+S) + L(L+N)\,p^2}.$$

In the expressions for $\tan\epsilon$ and $\tan\theta$ put $N = 0$, and they *both* become equal to

$$\frac{SLp}{R(R+S) + p^2 L^2}.$$

This shows that when $N = 0$ the current y in the branch S is as much ahead of the main current i as i is behind the impressed electromotive force, and hence that y agrees in phase with the impressed E.M.F. acting on the double circuit; in other words, the current in the branch S is entirely unaffected by being joined in parallel with an inductive circuit R; but if N is *not* quite zero, then the current in branch S *is* affected, as regards its lag, by the fact of being joined in parallel with an inductive circuit. The nature of this affection will be dependent on whether $SL - RN$ is positive or negative—that is, whether $\frac{L}{R}$ or $\frac{N}{S}$ is the greater—that is, whether the time-constant of the R circuit or the S circuit is greater. If $\frac{L}{R}$ is greater than $\frac{N}{S}$, then the current y in S is *ahead* of the main current i, but lags behind the impressed electromotive force. If $\frac{L}{R}$ is less than $\frac{N}{S}$, then the current y in S lags behind the main current i in phase, and, *a fortiori*, behind the impressed electromotive force. Let one of these divided circuits, viz., the one of resistance R, be a circuit in which it is desired to measure the *electrical power*. In the ordinary way of using the wattmeter the fine-wire coil, which we will assume has a resistance S, is placed in parallel with the inductive circuit, the thick-wire coil united in series with the inductive circuit. The main current i is thus divided between the inductive circuit R and the wattmeter fine-wire circuit S. The electro-dynamic action in the wattmeter is then one between a current in S, which we have called y, and one in the thick-wire circuit, which is the same as that in the inductive circuit R, which we have called x.

We have above arrived at expressions for the value of x and y.

The question then arises how far the indications given by the instrument, and which are due to the electro-dynamic action of the currents x and y, and proportional to their nume-

* *See* Lord Rayleigh "On Forced Harmonic Oscillations of Various Periods" (*Phil. Mag.*, May, 1886, p. 379.)

Digitized by Google

rical product, are proportional to the real power taken up in the circuit R.

The current x is the same as the current in R; hence the error, if any, will result from the current y in S differing in phase or in proportionality from the potential difference between the ends of the circuit R.

In the ordinary mode of calibrating the wattmeter the instrument would be applied to measure the power in a non-inductive circuit traversed by a known current, and having a known potential difference at its ends.

Hence, the real watts taken up in the circuit are known, and since the force required to bring back the movable coil to its initial position is proportional to the product of the currents in the fixed and movable coils, we have at once the desired constant of the instrument.

If a so calibrated wattmeter is applied to measure power in an inductive circuit, there are three different causes of error which may or may not neutralise each other, and which may cause the measured watts as determined by the instrument to be greater than, equal to, or less than, the real watts or power taken up in the circuit.

The first of these causes of error is due to the fact that the fine-wire circuit of the wattmeter always has a sensible inductance—that is, N is not zero. It is true it may be made very small, and can be made small by the device adopted by some makers of arranging the chief part of the wire resistance of the fine-wire circuit as a non-inductive resistance in series with a small inductive resistance which forms the movable coil. It follows that if E be the maximum potential difference during the period between those points to which the fine-wire circuit is attached, that the true average current in the fine-wire circuit is equal to $\frac{2}{\pi} \cdot \frac{E}{\sqrt{S^2 + p^2 N^2}}$, when subjected to a simple periodic E.M.F. of pulsation p. This quantity is not always proportional to E, but depends on p. The effect of the impedance of the fine wire circuit is then first to make the true mean current in it under periodic E.M.F. *less* than it would be if produced by a steady E.M.F. equal to the true mean of the periodic E.M.F. But in addition the impedance causes a lag in phase of the current in the fine wire circuit behind the phase of the potential difference between its ends. This is the second cause of error, and the effect of this lag is dependant upon the nature, whether inductive or non-inductive, of the circuit R. To dissect its action, first let us suppose the circuit R is non-inductive—that is, L is zero. The current x in it will, therefore, coincide in phase with that of the potential difference at the points of junction.

The current in S, viz., y, will, however, lag in phase behind that of the potential difference at the junction. The effect of this lag in S will be to increase the phase difference between x and y, and to diminish the cosine of this angle of phase difference. Hence, to diminish the product $\frac{XY}{2}$, cos δ, which measures the true mean product of x and y, X and Y being their maximum values, and δ their difference of phase. Since by assumption X agrees in phase with E, any reduction of the above product reduces the instrumental reading, and makes it less than the true-power reading. If, however, we have to deal with a circuit possessing inductance, and in which, therefore, there is a current x, of which the phase lags behind that of the potential difference of the junctions, then the lag in the current y in the circuit S, so far from increasing the difference of phase of x and y, may operate to bring them nearer into accordance, and hence to increase the instrumental reading over and above that decrease due to the first-named cause of error.

(To be continued.)

Owens College.—Prof. A. Schuster, F.R.S., has been appointed Langworthy professor of physics and director of the Physical Laboratory at Owens College, vacant by the death of Prof. Balfour Stewart.

CONVERSAZIONE AT THE SALTERS' HALL.

NEW FORMS OF SECOHMMETER AND AYRTON AND PERRY'S "MAXWELL" GALVANOMETER.

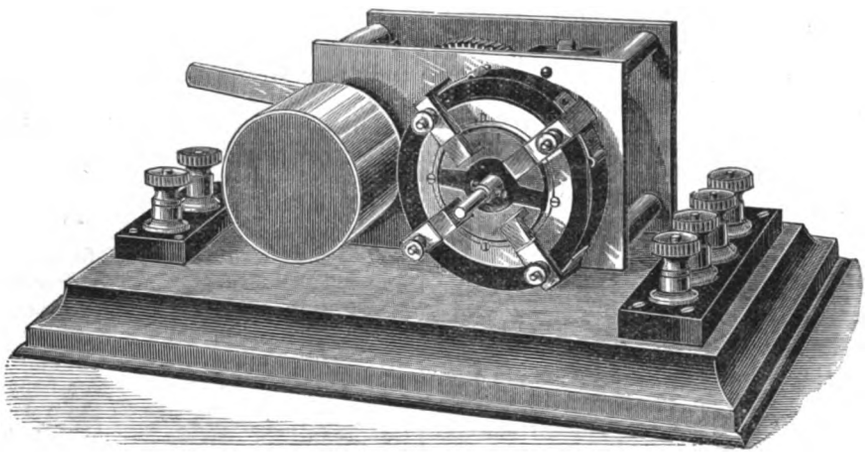
On Wednesday evening, the 16th inst., a *conversazione* was given by the Master and Wardens of the Salters' Company, attended by numerous visitors, amongst whom were the Lord Mayor and the various foreign burgomasters and *attachés* who were the guests of the Lord Mayor for that evening. Besides a vocal and instrumental concert, fairly rendered, there was a very fine loan collection of old and modern paintings, antiquities, and other works of art, together with a small collection of scientific apparatus, contributed partly by the City and Guilds of London Central Institution. Dr. Armstrong showed specimens of modern dyes and of fabrics treated with these dyes; Prof. Unwin the results of experiments with his 100-ton testing machine, and apparatus designed by himself for measuring small extensions of the samples under test in the machine. The bars of electro-deposited copper that had been broken in the testing machine were of especial interest to electrical engineers, since experiments showed that they possessed a vastly higher tensile strength than is possessed by ordinary copper. The direct-reading secohmmeter of Profs. Ayrton and Perry, with the recording mercury indicator, intended for absolute measurements of the coefficients of self and mutual induction, was shown. A later and cheaper form, intended to be used in the comparison of the coefficients of induction with one another, or with the capacity of a condenser, was also exhibited. This apparatus, which is constructed for the inventors by Messrs. Nalder, Bros. and Co., of Westminster, is seen, with the cover removed, in the accompanying figure. The wheel-work is driven by a handle at the back, not visible in the illustration; to the right is one set of commutator brushes for commutating the battery, while, at the back, is a similar commutator for commutating the galvanometer connections once between every commutation of the battery connections. To the left is seen a heavily weighted fly-wheel, and still further to the left a lever. On pressing this lever down, the driving spindle can be slightly pushed in or pulled out, which alters the gearing, so that ratio of the speed of commutation to the speed of rotation of the driving handle is increased or diminished fourfold. On releasing the lever, it engages with a flange on the driving spindle, and prevents any change in the relative speeds of commutation and of the driving handle. Both sets of four brushes are stationary, and are pressed by means of springs against the revolving commutators, which each consists of two flat pieces of brass separated by two small pieces of glass. In the position in which the commutator is seen in the figure the two upper brushes are electrically connected with one another, as are also the two lower. The brushes are constructed like the brushes of modern electric light switches, contact being made by the ends of a number of pieces of copper pressing against the moving commutator, since with this arrangement the wear of the brushes does not affect the relative times of commutation of the battery and galvanometer.

In the earlier forms of the secohmmeter only a make-and-break were successively made in the battery circuit and the circuit of a shunt to the galvanometer, but by the use of the double commutator in the new form of secohmmeter the sensibility of the arrangement is increased fourfold. For if there be any want of balance in the coefficients of self or mutual induction that are being compared with one another, or with the capacity of a condenser, the galvanometer receives an impulse in the same direction at every reversal of the battery, which impulse is twice as great and occurs twice as often as if the galvanometer needle received an impulse either only at the making or at the breaking of the battery circuit, as in the earlier forms of secohmmeter. The fly-wheels make 10 revolutions for every revolution of the handle, and, although by the simple alteration of the gearing, previously referred to, the commutators can be driven at will, so as to make either two reversals or eight reversals for every revolution of the handle, the ratio of the speed of the fly-wheel to the speed of the driving handle always remains the same, so that

Digitized by Google

the fly-wheel action remains constant. The driving handle can be conveniently turned by hand at speeds varying from about 60 to 200 revolutions per minute, producing with one arrangement of the gearing 120 to 400 commutations per minute, and with the other arrangement 480 to 1,600 commutations per minute; so that both the battery and the galvanometer circuits can be conveniently commutated from about 120 to 1,600 times per minute, the lower speeds being used for circuits having a large time constant, and the higher for circuits with a smaller time-constant. The exact range of commutation, however, is made different in the various secohmmeters intended for different purposes.

The uses to which the secohmmeter can be put have been fully developed in the Papers written by the inventors and by Mr. Sumpner and Mr. Rimington; and a further Paper, recently communicated by Mr. Sumpner to the Physical Society, and which we anticipate will appear in the *Philosophical Magazine* for June,* shows what valuable use can be made of the instrument for measuring the way in which the coefficient of self-induction of a transformer varies for different magnetising currents. In fact, as stated a year ago, the secohmmeter enables measurements which have hitherto had to be made during the make, or break, or reversal of a battery circuit—and which were, therefore, necessarily unsensitive—to be now made with the same high sensibility as has been accustomed to be obtained by the employment of a steady current in the ordinary measurement of resistances with Wheatstone's bridge.



New Type of Secohmmeter.

When the instrument is intended to be employed for absolute measurements of a coefficient of induction or the capacity of a condenser in terms of a resistance and a time, a speed indicator is attached to the spindle seen projecting from the commutator in the figure. But for comparison of the co-efficients of self or mutual induction with one another, or with the capacity of a condenser, no speed indicator is necessary.

Another use to which the secohmmeter can be put is the measurement of the resistance of a liquid which is liable to polarise with direct currents, but which, as is known, will not polarise with rapidly alternating currents. When the secohmmeter is used for this purpose the galvanometer commutator is adjusted so as to commutate at about the same instant as the battery connections are commutated, instead of one commutation being made between the other, as in the ordinary use of the secohmmeter. If now the secohmmeter handle be rapidly turned the resistance of the liquid can be measured without any error being introduced by polarisation, exactly as a resistance of a wire is usually measured with a Wheatstone bridge, the galvanometer needle steadily deflecting to the right or the left as the comparison resistance in the bridge is too high or too low.

A further exhibit was Profs. Ayrton and Perry's patented modification of the Maxwell or Deprez-D'Arsonval galvanometer, also constructed by Messrs. Nalder, Bros. and Co. In the ordinary Deprez-D'Arsonval galvanometer the deflecting couple for a given current passing round the suspended coil depends on the strength of the magnetic field on which the coil is suspended, while the controlling couple depends on the torsional rigidity of the wires supporting the coil, and which are twisted when the coil is deflected. Hence the sensibility of the instrument diminishes with any diminution in the strength of the magnetic field arising from a slow weakening of the permanent magnet attached to the instrument, or from a temporary variation of the strength of the field from the presence of some neighbouring *very* powerful magnet.

This defect, which renders the sensibility of this instrument as liable to vary as the sensibility of any other permanent magnet measuring instrument, and which has led to their almost entire disuse as *exact* commercial standards of current or difference of potential, has been overcome by Profs. Ayrton and Perry by introducing into the Deprez-D'Arsonval instrument the similar defect which existed in their old form of permanent magnet ammeter and voltmeter. In those instruments the action of the so called permanent magnet on the suspended needle produced the controlling couple; hence as the permanent magnet grew weaker the instrument increased in sensibility. Their improved Maxwell galvanometer is thus a combination of their permanent magnet instrument, having a suspended needle with the Deprez-D'Arsonval instrument with suspended coil, and it consists of a large stationary permanent magnet producing a field in which moves a suspended coil, round which passes the current to be measured. The connections of this coil, instead of having torsional rigidity, are made to have as little rigidity as possible, and the controlling couple is produced by the action of the stationary magnet on a number of little magnets rigidly attached to the moving coil. The deflecting couple, then, for a given current passing round the suspended coil, is, as in the ordinary Deprez-D'Arsonval instrument, proportional to the strength of the magnetic field; but the substitution of the small magnets rigidly attached to the coil for the torsional suspension wires makes the controlling couple also proportional to the magnetic field. Hence, the sensibility of this new form of galvanometer is unaltered for wide variations in the strength of the magnetic field.

In the first instruments on this principle, made by Mr. Jolin, of Bristol, for Profs. Ayrton and Perry, one single magnet only was attached to the suspended coil, but tests of the sensibility of the instrument showed that the compensation for considerable alterations in the strength of the stationary permanent magnet, although beneficial, was not very good. We understand that, although this little magnet was varied in shape and length, and attached successively to different parts of the moving coil, the results were still unsatisfactory, when finally the cause was ascertained by experiments being made by means of a very small exploring coil attached to a ballistic galvanometer to see how the strength of different parts of the magnetic field varied when the large permanent magnet was intentionally

* See also an abstract in *The Electrician*, April 27, 1888.

Digitized by Google

much weakened or strengthened. These experiments showed that on altering the strength of the permanent magnet, temporarily or permanently, the strength of the different parts of the field occupied by the suspended coil varied in very different ratios. Hence the application of a single small magnet to the coil generally either over or under compensated for changes in the mean strength of the field. By rigidly attaching, however, a number of small magnets on each side of the suspended coil this difficulty has been quite overcome, as the average controlling couple now varies practically in direct proportion with the average deflecting couple, no matter how the magnetic-field is disturbed. In fact, experiment shows that a 30 per cent. variation of strength of the field, which would of course produce a 30 per cent. variation in the sensibility of an ordinary Deprez-D'Arsonval galvanometer, does not produce more than about a six or seven per cent. variation in the sensibility of the new instrument, even when this 30 per cent. variation on the strength of the field is produced by the presence of a *very large* electro-magnet placed so as to produce much distortion of the fie'd. And five or six per cent. variations in the strength of the field produce no practical change whatever in the sensibility, so that the new Maxwell galvanometer, unlike all ordinary permanent magnet instruments, is compensated for all ordinary changes in the strength of the magnetic-field.

Some measuring instruments using Profs. Ayrton and Perry's well-known magnifying spring were shown, and a model voltmeter or ammeter for lecture purposes, based on the principle of their portable voltmeter for alternating currents, in which the increase of sag due to the small lengthening of the wire by heating produces a small alteration in the length of the spring, and a great rotation of the pointer was exhibited. The wire in this lecture room model was about 30in. long, and the application of the wires from two bichromate cells to its terminals caused the pointer to perform about four complete revolutions over a dial a foot in diameter, while one accumulator made the pointer move through twenty-four right angles.

Their magnifying spring has until quite lately been used mainly for the purpose of converting a small linear motion into a large angular one, but they have now devised a combination of a magnifying spring of large diameter and large pitch, with one of very small diameter and 45° pitch, for magnifying rotatory motions without friction or back-lash, and with a large range of direct proportionality; the specimen of the new combination shown at the *conversazione* magnifying a rotary motion about 120 times.

DISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

THURSDAY, MAY 17TH.

Mr. JOSEPH WILSON SWAN, examined by the ATTORNEY-GENERAL, said: I am the technical director of the Swan Electric Light Company, and have held that post since the formation of the company. I formerly carried on business as a chemist in partnership with Mr. Mawson. My business as a chemist was very varied, but a feature of it was the supply of philosophical and photographic and electrical apparatus and chemicals. My first thoughts as to producing light by electricity were after hearing a lecture by Mr. Stearn at Sunderland and Newcastle in 1845 and 1846. I did nothing in the carbonisation of paper and carbon till about 1848. In 1848 I carbonised strips of paper and coils of paper in charcoal in a potter's kiln. I packed them in charcoal powder. I packed them with charcoal because I had sufficient chemical knowledge to know that would prevent the burning away of the paper. They were carbonised in a fireclay crucible, and sometimes in common earthenware jars. They were carbonised in a pottery kiln belonging to Mr. Wallace, of Newcastle. The strips of paper were not only straight but were cut in the form of flat arches and ringlets. I carbonised those various forms. I made an attempt to render, after carbonisation, the strips incandescent under a vacuum. This was between 1848 and 1850. I did not succeed in raising the strips to incandescence. I do not remember doing anything more at that time that bears upon the question. I remember taking the thing up again about 1860. I did very much the same thing then as between 1848-1850, except that I made the pieces of carbon smaller. I had a better air-pump in 1860 than previously, the best mechanical air-pump that existed at that time. I had also a considerably larger battery power. I did succeed in making a flat carbonised paper arch bright red hot at that time under the receiver. I used a special shaped vessel to put the carbon in. When red hot the carbon bent, and broke on touching, the sole plate on which it rested. I had made a special insulated sole plate which would let the wires go through. I did not go any further at that date. I remember in the autumn of 1877 being introduced to Mr. Stearn. He is in court. He was a clerk in a branch of the Bank of England. I learned that he was very skilful in the use of the Sprengel pump. He was making radiometers and vacuum tubes of various kinds. My connection with Mr. Stearn continued through the years 1877, 1878, 1879, and 1880. He was residing during all that time at Rock Ferry, Birkenhead, and I resided at Newcastle. We communicated by letter when we did not meet personally. I kept all Mr. Stearn's letters to me and have the originals here. Mr. Stearn has told me he has not kept my letters to him. I am able from Mr. Stearn's letters as well as my own memory to fix the dates of certain things that happened between 1877 and 1880. I explained to Mr. Stearn, when introduced to him, my previous experiments. I asked him to mount some strips of carbonised paper for me between platinum wires, put them in a glass bulb, and exhaust it with a Sprengel pump. He agreed to do that. I remember in the end of 1877 sending him some carbonised cardboard strips. They were carbonised at the pottery kiln of Mr. Patterson, Gateshead, in an earthenware vessel. They were packed with powdered charcoal. No moulds were used; they were not necessary for my purpose. They were, in the first instance, simply straight strips about two inches long, and varied in diameter and breadth from one-eighth of an inch to one-fourth, and in thickness from that of paper to thin cardboard. [Shown drawing.] The sketch marked 14 represents the first form of tube with the carbonised strip that came back to me. Mr. Stearn made the first attempt to mount my carbonised paper strip on 30th October, 1877. One or two lamps of that kind came back. To the best of my recollection I was able to make them incandescent; the contact was very bad between the carbon strip and the platinum wires. There were two strips held by one end to the platinum wires and overlapping each other at the other end. That was to get over the difficulty of making a good contact between the platinum wires and the carbon, and also to obtain elasticity. This mode of mounting was really invented by Mr. Stearn's glass blower, who put them in the tubes. It was one of the attempts made at this time. Turning to a straight strip, witness said: I had in 1878 one, or possibly two, mounted forms like that. In it the strip of carbonised paper is mounted in a cleft, and the wires are extended slightly on either side. I had carbonised the strip and sent it to Mr. Stearn, and it came back to me as in the picture. I was not able to raise that lamp to incandescence. Turning to another drawing, witness said: I remember that the lamp represented here was made towards the end of 1878, just before my lecture at Newcastle. It is not quite the same as the Newcastle lamp. My recollection is that I received a lamp of this kind the night before I delivered my lecture in Newcastle. F I B 1 represents my Newcastle lecture lamp. The lecture was in February, 1879, and the night before I received the lamp we are now speaking of. That lamp was a strip of carbonised paper or thin cardboard; it had been completely electrotyped with copper by myself. It had a strip of platinum coil about the same length of the paper brass-soldered to each end. I sent two or three filaments mounted in that manner to Mr. Stearn. He had them mounted in a globe of glass; he then put them in a little bulb, and dissolved the copper away. The object of electrotyping with copper was to make a good contact between the carbonised strip and the platinum. I received two such lamps, one vacuum and the other open. I remember the vacuum having the current sent through it, becoming incandescent, lasting about half an hour, and then breaking. The other one sent me did not turn out a successful lamp. In the end of 1878 I received from Mr. Stearn a lamp like F I B 1. It has a thin, round carbon pencil. I showed that at the lecture in February, 1879. I have a very clear recollection of receiving the lamp the night before the lecture. I obtained the thin, round carbon pencil in the lamp indirectly from M. Carré. I had a lamp exactly like this a few weeks before 26th December, 1878. I sent a very strong current through it, and made it so hot that the carbon bent appreciably, the platinum supports were melted, and the carbon became detached, and fell unbroken, but bent, with a bright appearance of semi-fusion of the carbon. I first showed that lamp at a meeting of the Chemical Society in December, 1878, and then gave it to Mr. Proctor. I had a fire at my establishment on the 17th January, 1880. I have a singularly clear recollection of that date. I first made a thread lamp certainly not before the middle of the year 1880.

Is it true that in the year 1879 you had any thread lamps, either without the second loop or with the second loop, running in your engine room?—No, it is not true.

Prior to the fire had you produced any more successful lamp than F I B 1?—No; that was the most successful lamp we produced.

Examination continued: Through the year 1879 we were struggling to get lamps which would not break down, and our experiments were directed to that object. One great difficulty was the making of a good contact between the carbon conductor and the metallic conductor, and almost all our experiments were directed to conquer that difficulty. B S P 3 was made in 1879. I believe it was made after the Newcastle lecture. The copper spiral arose from our using the thicker carbon conductors, which were easier to manipulate, and required a stronger current than the carbonised strips of paper, and, therefore, the heat was greater. The spiral was used to carry off the heat. The carbon is a straight Carré carbon. In this lamp, because the carbon conductor is somewhat thick, copper and not carbon wires were used, and in order to make a perfect joint between the carbon and the glass the platinum cap was used to mediate between them. [Box produced with broken lamp.] That is the remains of a lamp in which the conductor was a Carré carbon of hairpin form, made in 1879. I produce a model of the hairpin carbon. [Shown letter.] That letter, dated 26th Nov., 1879, from Mr. Stearn to myself

Digitized by Google

contains a picture of the Carré carbon, described by Mr. Stearn, which recalls it to my recollection. I now produce a lamp made after the fire. The conductor is carbonised-parchmentised paper. There is a copper spiral inside. That lamp was made before I had made any carbonised thread lamps. Mr. Heaviside and Mr. Proctor made an entire mistake in saying they saw thread lamps in 1879. The outside number of lamps I had in 1879 would be twenty, possibly not more than ten. These we received two or three at a time from Mr. Stearn. Nobody else was making lamps for me in 1879 but Mr. Stearn. As soon as I began the thread lamp I used it always parchmentised. It was always successful. I exhibited them not before the middle of 1880. The parchmentised lamps were almost immediately a success. Towards the end of 1880 I made a considerable number. I ran them chiefly in the engine house at Moseley-street, and there was also one in my own house. The engine was put up in the March of 1879. It was got from Crossley Brothers. There was an extra fly-wheel put up for making the bearing on the axle more equal and also to drive another dynamo. Mr. Ridley's bill for the item is dated September 1st to 11th, 1880:—"Three men, 100 hours, at a countershaft, wheels, &c." In that same account there is a charge for wiring under date August 30th, 1880. The wires were those used in bringing current to the lamps that we did exhibit in the engine room. I remember soon after we began to run a difficulty arising from unsteadiness. A well-known irregularity existing in the gas engine gave us some difficulty, and we corresponded with Mr. Crossley on the subject. There is a letter dated September 4th, 1880, which would be written a month or two after we experienced the difficulty. Mr. Heaviside and Mr. Proctor had probably seen the lamps in my place of business in 1880. I remember Mr. Stearn rendering me his account in the end of the year 1879. All my lamps were blown for me by Mr. Stearn. I never produced a lamp with a double turn in it before I had the thread lamp. I went to Mr. Stearn's two or three times. I was there on 16th January, 1880, and received a telegram telling me of the fire whilst I was at his house. I was in the act of seeing one of the lamps run when the telegram was put into my hand. It was a Carré carbon lamp. I can state very distinctly it was not a thread lamp. At my visits to Mr. Stearn's I never saw or was shown, prior to the fire, any thread lamp. In conjunction with Mr. Stearn I made experiments about driving out the occluded gases, in order to make the lamp more durable. I filed a specification on the 2nd January, 1880, for driving out the occluded gases. I did not know before I filed that that it had been described in the specification of Mr. Edison in 1879. That was the patent on which the Swan Company attempted to take proceedings in the Woodhouse and Rawson action.

Cross-examined by Sir HORACE DAVEY: I am a director of the Swan United Electric Lighting Company (Limited). They hold a large number of shares in the company who are at present the plaintiffs. I hold a number of shares in the plaintiff company indirectly. I do not think I hold any official position in the Edison and Swan United Electric Lighting Company (Limited). If I could render any service to the Edison and Swan Electric Lighting Company I would do so, but I hold no office in the company. The plaintiff company was the result of an amalgamation of the Edison Electric Light Company with the Swan Electric Light Company, made in October, 1883.

Was that amalgamation the result of an action brought by the Edison Company against your Company?—I believe it was.

Do you not know it was?—I know that other considerations entered into the question besides that.

I think the share capital of the amalgamated companies was divided between the two companies?—Yes.

Is it not the fact that the Edison Company got 45,000 shares fully paid up, or partially paid up, and the Swan Company 61,400?—I cannot speak to the fact. My impression was that the figures were 60,000 and 40,000.

The Swan Company 60,000, and the Edison Company 40,000?—Yes, I think so.

I think Edison's Company were suing the Swan Company for infringment of patent in November, 1879?—I think they were.

Do you know they were?—I cannot distinctly call to mind the position of the question of litigation at this moment.

You told us F I B I was a Carré carbon?—Yes.

Do you know how Carré carbons are made?—No, I do not know from absolute knowledge; but I have my idea on the subject.

Do you know that the Carré carbon received its present shape before carbonisation?—No, I do not know; I think it probable.

Witness was next asked if he remembered the telegram from Mr. Edison in October, 1878, sent to this country, and the learned counsel having read a quotation from Mr. Swan's lecture at Newcastle on the 4th February, 1879, asked, Was it the platinum lamp which was referred to in Mr. Edison's telegram which was going to revolutionise the world?—It was the platinum lamp.

It proved a complete failure?—I do not know that.

It has been superseded by the carbon lamp?—Yes.

Dealing next with the lectures of Mr. Swan the learned counsel asked, did you in addition to exhibiting a lamp at either of these lectures also exhibit some unmounted carbons?—I have not the slightest recollection of that.

Did you not exhibit some horseshoe-shaped cardboard or paper carbons?—I am able to say I did not.

Did you use horseshoe-shaped carbons during the year 1879 in incandescent lamps?—Probably towards the end of 1879 I did make some hairpin-shaped carbons.

Are you prepared to say you did not during the period from the beginning of July to the end of October, 1879, or some part of that period, make lamps with that hairpin-shaped carbon conductor?—I am not prepared to say I did not.

Did you during the period which I have named, and referred to by Mr. Heaviside, send lamps with that hairpin-shaped carbon in them to Mr. Heaviside to be tested?—I do not know.

Do you not think it probable that the lamps to which Mr. Heaviside refers with the horseshoe carbon had that hairpin Carré carbon in them?—I think it is just as probable he is mistaken altogether as to seeing the lamps at all. He is absolutely wrong as to seeing any lamps in the horseshoe-shaped carbons made with carbonised cardboard.

I am taking you away from that, if you will be kind enough to follow. Mr. Heaviside's impression is that they were carbonised cardboard, because you told him so?—I have no confidence in his recollection.

That is for his lordship to judge. You have already told me you are not prepared to say you did not make lamps with that hairpin-shaped cardboard in them during the period I have mentioned?—Yes.

Are you prepared to say you did not send lamps of that character with hairpin-shaped cardboard in them to Mr. Heaviside to be tested during that period?—I am not prepared to say that; I think it is extremely doubtful.

Take that hairpin-shaped carbon model in your hand, and I ask you, do you not think that a very fair filament?—I am not an authority on filaments.

Mr. Swan, is there any gentleman in the world who has delivered so many lectures about filaments as you have done? Tell me fairly, is not that a very fair filament? You know perfectly well that the word filament has come to have a technical and special meaning, and it is now used as simply equivalent to a conductor, without reference to science.—If you ask me if this is a good specimen of a filament in that sense, I say I cannot answer the question in that form.

What should you say was the diameter?—It is the twenty-fifth part of an inch.

Surely it is more than that?—No, it is not. I have had it very accurately measured.

In 1879 was not that a very fair filament?—The word filament was not used at that time. There was no fair or unfair filament at that time.

I think you were troubled with smoke in your lamp?—Yes; one of the difficulties we had to contend with was blackening of the bulbs.

You ordered these carbons from Carré?—I ordered them from Carré, through Breguet.

Did they turn out successful?—No, I cannot call to mind a single successful lamp made with these carbons.

Was that on account of the occluded gases?—No, chiefly on account of bad contact with the platinum wires.

Can you give me the date when you ordered the hairpin-shaped carbons from Breguet?—Approximately, I think it was in the spring of 1879.

And could you give me the date approximately when you received them?—I am sorry to say I cannot.

I suggest it might be a month or six weeks afterwards?—It might be.

And I suppose you did not order them before you wanted them?—No.

And did you not when you got them make use of them?—That is extremely doubtful, because I was engaged in other business that was very pressing, and Mr. Stearn was very often kept waiting a considerable time before I sent him the material to carry on the experiments. And it is by no means certain I immediately sent him the hairpins after I received them. The contrary is highly probable.

The smoke in the lamp engaged the attention of yourself and Mr. Proctor?—The only assistance I received from Mr. Proctor in reference to the blackening of the globes was his investigation on the nature of the deposit on the broken lamp shown at the Chemical Society.

On the 2nd January, 1880, you took out a patent for the purpose of getting rid of that difficulty by a process now known as running on the pumps?—Yes.

Did you claim that as a process of running on the pumps for the purpose of getting rid of the occluded gases?—Yes.

On the 18th January, 1880, do you remember writing a letter to a publication called *Nature*?—I remember writing such a letter.

Having quoted the letter, Sir HORACE DAVEY asked, Is it not a fact that during the six months before writing that letter you had been experimenting with cardboard?—No, the improvement I referred to in that letter which led me to believe I had removed the difficulty that stood in the way of producing an incandescent lamp was the running on the pumps, which I took a patent for directly afterwards.

Did you not intend by that letter to convey to the public that you had succeeded by means of your improvements in producing an incandescent lamp with a horseshoe cardboard conductor?—The letter is absolutely correct in every particular. I do not know that I can explain it better than any one else.

Then, after having conquered the difficulty, by running on the pumps, of getting rid of the occluded gases, you were in a position to say, "I have now completely conquered the difficulty which led to previous failure, and am now able to produce a perfectly durable incandescent lamp by means of carbon"?—That was my belief at the time.

And was not your belief well founded?—I did look upon the want of running on the pumps as the greatest barrier in the way of success of making a thoroughly efficient incandescent lamp, but I afterwards found there were several difficulties before that one to be conquered.

You now say that the letter was not perfectly accurate, or that it was too sanguine?—I still adhere to the statement, which is perfectly accurate. The other difficulties I refer to are the difficulties of getting a good contact, and also as to the material to be used for the carbon.

On the 20th January you took out a second patent?—Yes; No. 250 of 1880.

This is a patent for improvements in electric lamps. You did not mean to suggest at this date that there was any novelty in an incandescent lamp consisting of a glass bulb exhausted, of a vacuum, and with a carbon

Digitized by Google

conductor between leading wires which were sealed into the globe?—No, I did not intend to suggest that there was any novelty in that combination.

Nor did you intend to suggest that any particular size of carbon would suggest a novelty?—I made no suggestion bearing in any way upon this point.

Was it not in 1879 exactly on the working of these details that the success of the incandescent lamp depended? I am now addressing you as the most experienced electrician in the world.—I have no objection to say that the success of the incandescent electric lamp will depend very much upon the working out its details.

And was not that, in November, 1879, all that remained to be done to make the incandescent electric lamp a success?—No, I think not.

What else was there?—Nothing but the careful working out of details

After luncheon witness was cross-examined by Sir HORACE DAVEY as to his patent of the 27th Nov., 1880, referring to parchmentised thread. After taking out the patents he delivered some lectures on incandescent lighting. He delivered one in October, 1880, in Newcastle. The learned counsel having quoted from the lecture the passage: "There were two great difficulties, one was the rapid wearing away and consequent breaking of incandescent carbon, and the other the obscuration of the lamp by black smoke," witness said these were the difficulties to be surmounted as far as he understood that subject at that time.

Having quoted further from the lecture, Sir HORACE DAVEY asked: Were you not representing to the people that the lamp which you produced at this lecture was the same lamp as the one of two years ago, with the improvements you mentioned of vacuum, contact, and material?—I say what I intended to convey was that it had the elements of simplicity; that it had glass, platinum wires, and a carbon conductor, and so far as the elementary character of the combination went that it was identical with Edison's; but that is as far as I go. I simply limit my expression of opinion as to the identity of the two things, and the simplicity of the combination of the conductor, the glass, and the platinum wires.

Sir HORACE DAVEY next quoted extracts from a Paper read by witness before the British Association at York, and reported in *The Electrician* on the 17th of September, 1881. Witness said he was perfectly certain he did not show any lamp containing carbonised paper carbon either to Sir Wm. Armstrong or Sir Wm. Thomson.

Was it not in the early part of 1879 that Mr. Stearn made you that bulb which you have described?—It is perfectly true.

But you do not think you showed it either to Sir William Thomson or anybody else?—I am quite sure I did not.

I ask you whether the lamp produced by Mr. Edison referred to is not the lamp made by him after his patent of November, 1879, and subsequent patents?—I should think it is.

I ask you whether it is not a fact that the lamp produced by Mr. Stearn was identical with that in all essential particulars?—I was referring to the combination of the carbon, platinum, and glass, and, in so far as the combination of these three elements is concerned, I look upon it as identical.

At that time you considered Edison's lamp identical with yours in all essential particulars?—Only in so far as it was of simple construction of glass, platinum and carbon.

I do not know what the practice of the Editor of *The Electrician* is, but was this Paper sent to you for correction before being published?—No; I do not think I saw it.

Perhaps you sent your MSS. to the Editor of *The Electrician*?—I do not know.

I refer you next to a lecture delivered at the Royal Institution, Albemarle-street, on the 10th of March, 1882, Sir Frederick Bramwell in the chair. You then produced your carbon filament from carbonised cotton thread, and pointed out the great beauty of it?—Yes.

You formed a company, called the Swan Electric Company (Limited), for making incandescent lamps and working the patent which you had taken out?—Yes.

And a company was formed for working the Edison patent called the Edison Electric Light Company (Limited)?—Yes.

In the year 1882 an action was brought by the Edison against the Swan Company?—Yes.

Will you accept it from me that that action was complaining of an infringement of the Edison patent in the year 1879 by the Swan Company?—I do not know.

Witness was then examined as to his affidavit in the case sworn on the 27th July, 1882, and filed on the 28th of the same month.

Shown the lamps, and asked, would either of these represent the Swan lamp at that date which was charged with the infringement?—I think these are long anterior to that date.

Are they substantially the same?—No; the lamp being made at that time was a good deal different from either of these.

The re-examination of the witness by the ATTORNEY-GENERAL had not concluded when the Court rose at 4 o'clock, to resume consideration of the case on Wednesday, the 30th inst., at 10:30.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended May 18th, 1888, are estimated at £5,326.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month to May 15th, 1888, are £2,802, as compared with £2,299 in 1887.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended May 18th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,405.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* THE PROPRIETORS.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

THE PORTRAIT OF SIR JOHN PENDER.

To meet the desire of those who wish to frame the Steel Plate Portrait of SIR JOHN PENDER, given with our issue of the 27th April, a limited number of impressions have been taken on large paper, and can be obtained in a neat black and gold or carved brown frame, price Four Shillings each.

Orders to be addressed to The PUBLISHER, "Electrician" Office, 1, Salisbury-court, Fleet-Street, London, E.C.

VOLUME XX. OF "THE ELECTRICIAN"

NOW READY. Bound in cloth, price Ten Shillings and Sixpence. Also Cases for Binding, price Two Shillings.

ELECTRIC FIRE-ALARMS.

The pressure of more immediately urgent, if not intrinsically more important, subjects for discussion has prevented us giving until now the attention it deserved to Mr. VON TREUENFELD'S Paper on Fire-Telegraphy, read at the Society of Telegraph-Engineers and Electricians before the Easter holidays. From the personalites and recriminations aroused by the issuing of the Society's "Rules" for the prevention of fires due to electricity, commented on in these pages last week, it is pleasant to turn back to Mr. VON TREUENFELD'S record of the services electricity has been rendering in reducing the destructive effects of fires, from whatever causes they may arise. The introduction of every new illuminant is always an additional element of danger, against which it is necessary to devise new precautions; but as regards the employment of electricity for lighting purposes it is satisfactory to know that not only is it safer than any illuminant it may supersede, but that the current which supplies it affords the most efficient safeguard against any serious consequences arising from its use. We have not, however, had to wait the development of electric lighting for this assurance. Electric fire-alarms in one form or another have been in practical use for upwards of thirty years, their introduction into the city of Berlin dating even as far back as 1849; and they have gradually, though slowly, extended their operations into almost every considerable town of the civilised world. Mr. VON TREUENFELD, who eleven years ago gave us the history of this valuable application of electricity down to that date, has now furnished complete statistics of its operations to the end of 1886. As a mere account of the rise and progress of an important electrical industry his Paper is extremely interesting; but as a contribution to the

Digitized by Google

fire statistics of the world its economical importance can hardly be overestimated.

The chief value of these statistics lies in the fact that they have been compiled by an independent authority whose sole aim was to get at the actual figures, and to deduce whatever useful lessons might be learnt from the comparison of serious fires with the means available for preventing their occurrence. That Mr. VON TREUENFELD is an enthusiast for fire-telegraphy is obvious enough; but that he is not blinded to its shortcomings is equally evident from the candour with which he confesses its failure to lessen the death rate attending conflagrations—a subject on which we shall have something to say further on. From causes which are intelligible only to the insurance world its statistics of fires continue to be wholly untrustworthy; and in respect to the relation between fire telegraphs and the speedier extinction of fires the insurance offices afford us no information whatever, their attitude being one that on a less serious subject might be called cynical indifference. They are not at all anxious to prevent small fires, and they desire to avoid contributing anything for the prevention of large ones. It is their business to indemnify; it is not at all their business to lessen the risk. People would not insure their property if it were secured against fire; and as insurance offices subsist on insurance they are not in the least anxious to diminish the motive for that prudential transaction. As their representatives did not scruple to publicly avow these considerations in the discussion following Mr. VON TREUENFELD'S Paper, we are justified in reproducing them here, if only for the purpose of showing how little we can rely upon their figures, and how much we are indebted to the indefatigable industry of Mr. VON TREUENFELD. At the same time, it is only fair to add that some of the Fire Insurance Offices take higher views of their duty towards the public in this matter.

Now, the one broad fact which comes out after a careful study of the author's figures, making every allowance for the criticism to which the meeting subjected them, is that the number of serious fires has diminished in proportion as the electrical means of signalling them has been increased. The term "serious" in this relation is variously defined in different countries and even in different towns. Every fire is serious if it is not put out, but to insurance offices no fire is serious if it does not seriously tax their resources. A safer guide is to be found in comparing the amount of property destroyed at different periods; and perhaps the most trustworthy, certainly the most valuable, part of Mr. VON TREUENFELD'S statistics is that which shows how the aggregate destruction of property has been reduced in recent years, notwithstanding the large increase in the number of fires which break out. Taking New York as an illustration, the number of fires from 1872 to 1876 was 7,274, destroying 14,668,513 dollars' worth of property. Ten years later the fires had increased to 11,470, but the destruction had only amounted to $18,292,695. That is to say, the average loss by each fire had decreased from $2,017 to $1,595. In Brooklyn the results are still more striking. There, although the number of fires has doubled since 1876, the loss of property amounts now to only about half what it did then; and this result is attributable mainly, if not solely, to the increase of public fire-alarm points, which in 1886 numbered 321, whereas in 1876 they numbered only 22.

When it is considered that the most wasteful of all forms of destruction is the destruction of property by fire, the saving thus effected by the instrumentality of electric signalling is something to be proud of, and something which the public are not likely to ignore, whatever may be the sentiments of the insurance offices. One of their representatives calmly told the meeting that what they did not mind was plenty of fires in the suburbs to keep up the demand for insurance policies; but that they were quite alive to the importance of diminishing the ravages of fire in the City, where damage to property was often very serious indeed. Probably this speaker did not at the time reflect on the fact, which nevertheless is indisputable, that the fatalities attending fires are connected chiefly with suburban or residential fires, not with the business premises of the City. The painful confession had to be made by Mr. VON TREUENFELD that with the increase in the number of fires, notwithstanding the abatement in their destructiveness, loss of life has gone on proportionately increasing. And this circumstance calls for the remark that while the efforts to protect property have been rapidly augmented, those for the preservation of life in the residential suburbs have been comparatively neglected. Perhaps the most valuable result of Mr. VON TREUENFELD'S Paper was the speech made upon it by Captain SHAW, the chief of the London Fire Brigade. Every electrician interested in the construction of fire-alarms, either of the automatic or call-station type, ought to give the carefullest attention to Captain SHAW'S remarks, which are fully reported in the current number of the Society's *Journal*. The much-boasted automatic systems of America he showed to be utter delusions, and their adoption in England to be almost worse than useless. The automatic kind are largely used in America; but that, Captain SHAW assures us, is not because of their reliability, but because they are sold by the same people who are the insurance agents, and who work the two businesses together very profitably to themselves, though with small advantage to the public. The street fire-call points answer admirably, but are subject to the serious inconvenience of encouraging false alarms. Of 1,195 calls from these points in London last year 375 were false, and 170 of them were traced to malice or mischief. In the United States the proportion of false to genuine alarms appears to be still greater. Here, then, is an excellent opening for electrical ingenuity; and the plain way in which it has now been stated ought to render the problem not very difficult of solution. It might be easy to invent an automatic handcuff for the frivolous persons who ring fire-alarm bells without any provocation. It would be far more meritorious, though seemingly more difficult, to devise an automatic fire-alarm which will awake the inmates of a house when a fire really does break out, and so save their lives, whatever becomes of their property. In this way the electricians might do what no insurance office can, or, apparently, cares to do.

A NEW ALTERNATE-CURRENT DYNAMO.

The machine which is illustrated by the first of the accompanying figures is being brought out by the Anglo-American Brush Electric Light Corporation, principally for use in connection with distribution on the transformer system. It is one of a new type, the invention of Mr. W. M. Mordey, of the Brush Corporation, and gives an output of 35,000 to 40,000 watts, the terminal potential difference being 2,000 volts. The speed is 650 revolutions per minute. Fig. 2 shows the armature, which is stationary, and consists of a number of coils of narrow copper ribbon, wound on cores of non-conducting material. Each coil is bolted at the broad end between two brackets, the ends of the conductor being brought out through porcelain insulators.

The brackets are then bolted to a gunmetal supporting ring, the coils being thus rigidly and securely held in position by metal supports, which in no part come between the poles, and are, in fact, practically out of the magnetic-field. By this means

Digitized by Google

eddy currents are almost entirely avoided, any loss from this cause being still further reduced by the use of German silver for the brackets and bolts, the high-resistance of this alloy preventing the generation of local currents of more than a very small amount. The gunmetal supporting ring, which is bolted to the bed-plate of the machine, is in two portions, being divided in a vertical diametrical line. These two parts, after having received the coils, are bolted together and to the bedplate, the field-magnet being first placed in position. This design provides ample facilities for repairs. It allows not only of single coils of the armature being quickly removed and replaced, but also renders it easy to take out one-half or the whole of the armature. It is of the first importance in all electric lighting work, especially for central stations, that the machinery should be planned not only with a view to the prevention of a breakdown, but also to permit of any necessary repairs being quickly carried out. It will be seen that in this armature both these ends have been very satisfactorily attained.

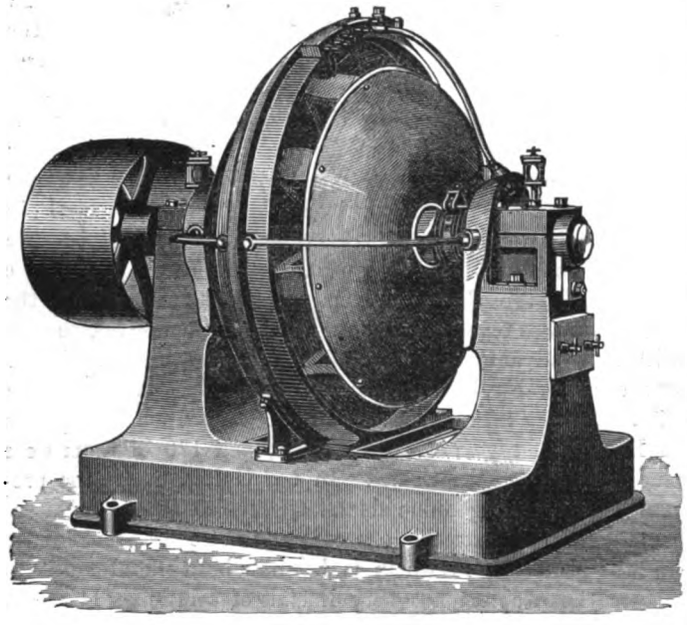

FIG. 1.—Mordey Alternator.

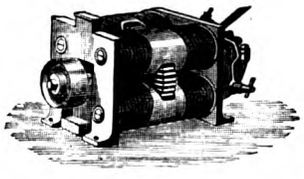

FIG. 1A.—Victoria Exciter.

The field-magnet (Fig. 3) cannot be said to bear any resemblance to any form of field with which electric engineers are familiar. It consists of a single electro-magnet, built up as follows:—A short cylinder of iron, through the axis of which the shaft passes, forms the core of the magnet, and round this core is wound the exciting coil. Against each end of this cylinder is placed a cast-iron piece, of a form which will be best understood from Fig. 3. Each casting has a number of horns or arms—nine in the machine illustrated—which radiate from the shaft and central part of the casting, and then bend over, forming nine pole-pieces on each side of the armature. These horns on one side, as will be seen, approach within a very short distance of those on the other side of the armature, and in this very narrow polar gap or slit the armature is held, the entire field-magnet revolving with the shaft on which it is mounted. The ends of the exciting coil are connected to "collector" rings on the shaft, which are shown to the right of the figure. These may be dispensed with, and the exciting coil as well as the armature may be stationary; but it is preferable, for mechanical reasons, to attach the winding to the rotating magnet.

It will be observed that this form of field-magnet is very simple. A single exciting coil suffices for a machine of any size, speed, or number of alternations. Besides its peculiarity of form it differs from the usual arrangements in that it has poles of one sign only on each side of the armature; thus the magnetic leakage between adjacent poles on each side is absolutely *nil*, a condition widely different from that of machines having the usual arrangement of alternate polarities, in which the leakage is very considerable.

By revolving the field-magnet, instead of the more delicate armature, safety and steadiness of running are secured, the heavy magnet acting as an excellent fly-wheel, and effectually neutralising any pulsation due to irregularity in the stroke of the engine. This is a point of some importance where slow-speed engines are used. Further, as the parts revolving at the highest velocity are simple solid iron masses of the strongest description, not subject to heating and having no copper wire to expand and fly out, the electrical and mechanical considerations which in ordinary dynamos usually render slow

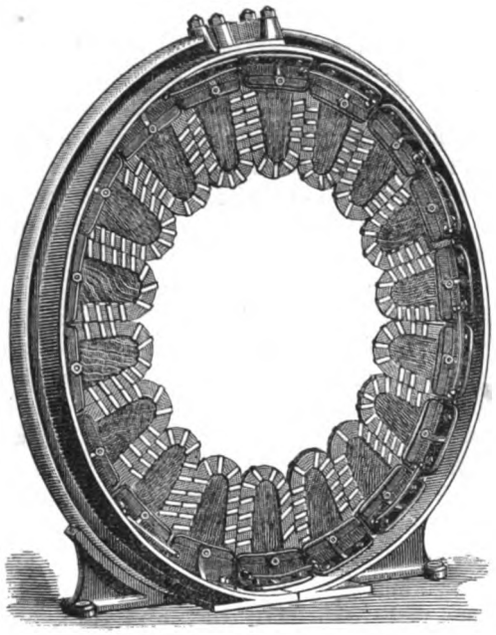

FIG. 2.—Armature of Alternator.

speed advisable do not here apply. The armature being stationary, the coils have to be supported only with a view to resisting the drag of the field. This renders insulation a matter of comparative simplicity, and is of great importance in high-tension work.

The Mordey Alternator is shown in its complete form in Fig. 1. The field-magnet is almost entirely hidden by sheet-metal covers, which have for their object the prevention of air-disturbance by the horns. The armature terminals, which are not seen in the figure, are at the upper part of the supporting ring. The thrust bearing is adjustable longitudinally for the purpose of enabling the field to be placed exactly symmetrical with regard to the armature. The alternator is very nearly self-regulating in itself, as is shown by Fig. 4, which is the characteristic of the machine throughout a range of 37,000 watts. From this curve it is clear that, practically, the whole of the load—or, say, 600 lamps—might safely be turned off without danger to any remaining lamps, and that a large proportion of the load—certainly 50 per cent.—could be turned off without attracting notice on the rest of the circuit. It is, therefore, not considered

Digitized by Google

necessary or desirable, except under special circumstances, to provide other than a simple hand-regulation at the dynamo for the purpose of controlling the potential difference. Sudden and violent fluctuations of the lights are impossible with this machine, and an occasional touch of the resistance-regulator as the load comes on or off meets all practical requirements. It is only in the case of machines whose potential curve is a rapidly falling one that it is necessary to resort to automatic control. There is no doubt that by avoiding the use of additional apparatus of this sort the chances of temporary interruption are reduced. The small Victoria dynamo, used as exciter, is shown by Fig. 1A, which is to same scale as the alternator.

By the arrangement of the armature coils it is easy to obtain various combinations if desired. This circumstance is made use of for simplifying the measurement of the potential. Instead of taking the reading across the terminals, which would necessitate the use of an electrometer, or a very high resistance voltmeter, an ordinary voltmeter, indicating to 100 or 150 volts, is placed across one of the coils, the machine being fitted with a special pair of voltmeter terminals for this purpose. The indication thus obtained, multiplied by the total number of armature coils, gives the potential difference between the armature terminals. The voltmeter may, if desired, have its dial marked to directly indicate the total potential difference.

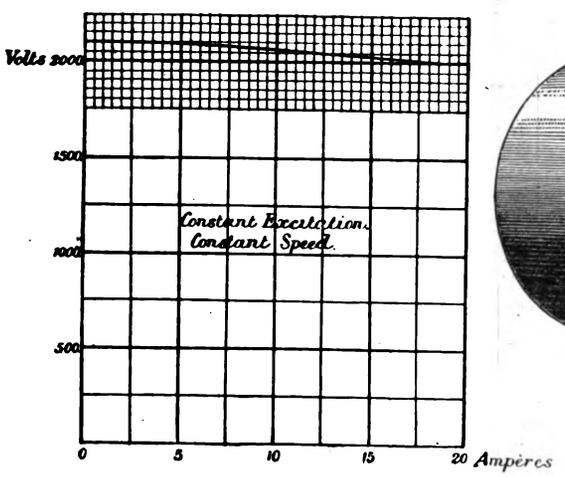

FIG. 4.—Characteristic of Mordey Alternator.

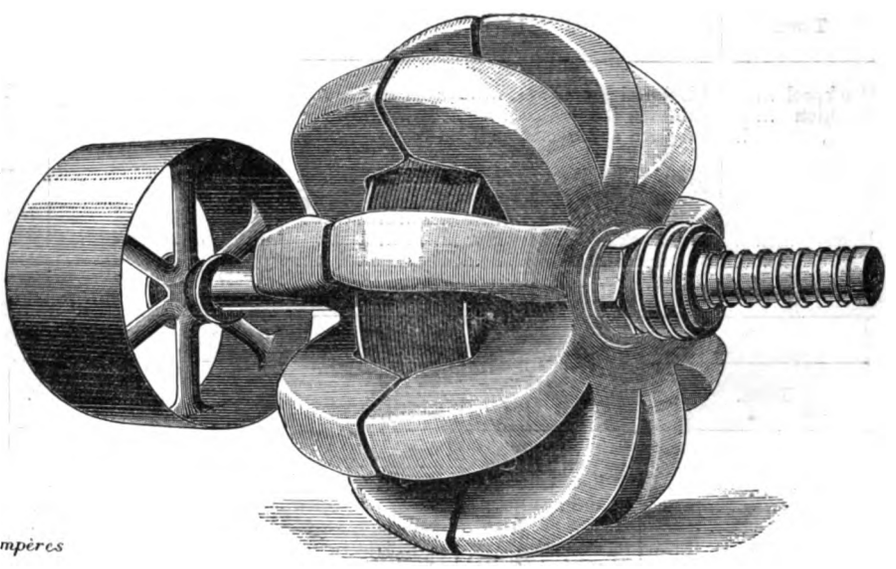

FIG. 3.—Field Magnet of Alternator.

We understand that this dynamo of 50 to 60 horse-power—the first of its type—was built directly from the first design, without recourse to any preliminary experiments.

ON THE MAGNETIC QUALITIES OF NICKEL.*

BY J. A. EWING, F.R.S., AND G. C. COWAN.

The experiments described in the Paper were made with the view of extending to nickel the same lines of inquiry as had been pursued by one of the authors in regard to iron (*Phil. Trans.*, 1885, p. 523). Cyclic processes of magnetisation were studied, in which a magnetising force of about 100 C.-G.-S. units was applied, removed, reversed, again removed, and re-applied, for the purpose of determining the form of the magnetisation curve, the magnetic susceptibility, the ratio of residual to induced magnetism, and the energy dissipated in consequence of hysteresis in the relation of magnetic induction to magnetising force. Curves are given to show the character of such cycles for nickel wire in three conditions: the original hard-drawn state, annealed, and hardened by stretching after being annealed. The effects of stress have also been examined (1) by loading and unloading magnetised nickel wire with weights which produced cyclic variations of longitudinal pull, and (2) by magnetising while the wire was subjected to a steady pull of greater or less amount. The results confirm and extend Sir William Thomson's observation that longitudinal pull diminishes magnetism in nickel. This diminution is surprisingly great; it occurs with respect to the induced magnetism under both large and small magnetic forces, and also with respect to residual magnetism. The effects of stress are much less complex than in iron, and cyclic variations of stress are attended by much less hysteresis. Curves are given to show the induced and residual magnetism produced by various magnetic forces when the metal was maintained in one or other of certain assigned states of stress; also the variations of induced and residual magnetism which were caused by loading and unloading without alteration of the magnetic field. Values of the initial magnetic susceptibility for very feeble magnetising forces are stated, and are compared with the values determined by Lord Rayleigh for iron, and the relation of the initial susceptibility to the stress present is investigated. The Paper consists mainly of diagrams, in which the results are graphically exhibited by means of curves.

*Abstract of Paper read before the Royal Society, May 17th, 1888.

JUVENILE LECTURES.

THE APPLICATION OF ELECTRICITY TO LIGHTING AND WORKING.*

BY W. H. PREECE, F.R.S.

Lecture II.

(Continued from page 43.)

The next purpose that electricity is used for to which I want to draw your attention, is that of the transmission or propulsion of coaches on railways. I have taken the trouble to find out the various railways and tramways in America, in Great Britain, and on the Continent, that are now worked by means of electric currents. A list of them is given in the Table on next page.

You will see how greatly and how rapidly this great power that electricity gives us is being utilised for useful purposes. One of the earliest lines upon which the power was used was the Portrush and Bushmills Railway, in Ireland (Fig. 10). Near Portrush there is that wonderful formation of rocks known as

* A course of two Lectures delivered before the Society of Arts on January 4th and 11th.

ELECTRIC TRAMWAYS IN AMERICA.

THE "ELECTRICIAN" GIVES THE FOLLOWING LIST OF ELECTRICALLY-WORKED TRAM LINES NOW IN ACTUAL USE IN THE UNIEED STATES:—

Town.	Line.	Conductors.	Length of Line.	System.
Appleton, Wis.	Appleton Electric Street Railway	Overhead	4½ miles	Van Depoele, 5 motor cars.
Asbury Park, New Jersey	Lea Shore Electric Railway	,,	4 ,,	Daft.
Baltimore, Md.	Union Passenger Railway Company	,,	...	Daft.
Bellevue, Pennsylvania	...	...	½ ,,	—
Binghampton, New York	Washington Street and State Asylum Electric Railroad	Overhead	5½ ,,	Van Depoele.
Denver, Colorado	Denver Tramway Company	Conduit	4 ,,	Short-Nesmith, series.
Detroit, Michigan	Detroit Electric Railway Company	Overhead	2 ,,	Van Depoele, 4 motor cars.
,, ,,	Highland Park Railway Company	,,	3 ,,	,, ,, 2 ,, ,,
Gratiot ,,	Gratiot Electric Railway Company	,,	...	,, ,, 1 motor car.
Ithaca, New York	Ithaca Street Railway Company	,,	...	Daft.
Kansas City, Mobile	Kansas City Electric Railway Company	...	...	Henry.
Lima, Ohio	Lima Street Railway Motor and Power Company	Overhead	6½ ,,	Van Depoele, 7 motor cars.
Los Angeles, California	Los Angeles Electric Railway Company	,,	5 ,,	Daft, 4 motor cars.
Mansfield, Ohio	...	,,	...	Daft.
Montgomery, Alabama	Capital City Electric Street Railway Company	,,	11 ,,	Van Depoele, 20 motor cars.
Port Huron, Michigan	Port Huron Electric Railway Company	,,	2¾ ,,	,, ,, 3 ,, ,,
Richmond, Virginia	Richmond Union Passenger Railway	,,	...	Sprague motors.
St. Catherine's, Ontario	...	,,	6 ,,	Van Depoele.
Scranton, Pennsylvania	Scranton Suburban Railway Company	,,	2½ ,,	Van Depoele, 3 motor cars.
Wichita, Kansas	Wichita Riverside and Suburban Railway	,,	4 ,,	,, ,, 6 ,, ,,
Windsor, Can.	Windsor and Wakerville Electric Railway	,,	1½ ,,	,, ,, 1 motor car.
Woonsocket, Rhode Island	Woonsocket Street Railway Company	,,	...	—

ELECTRIC TRAMWAYS IN GREAT BRITAIN.

Town.	Line.	Conductor.	Length.	System.	Power.
Blackpool	Blackpool Tramway	Buried central rail.	2 miles.	Holroyd Smith.	Steam.
Brighton	Brighton Beach	Rails.	1 ,,	Volk.	Gas.
,,	Brighton and Shoreham Tramway	Nil.	4 ,,	Electric Traction Syndicate (Accumulators).	Steam.
Glynde	Glynde Clay Pits	Open.	1 ,,	Telpherage.	,,
London	North Metropolitan Tramways (Stratford and Manor Park)	Nil.	4 ,,	Elieson (Accumulators).	,,
Newry	Bessbrook and Newry	Raised central rail.	3¼ ,,	Hopkinson.	Water.

the Giant's Causeway, and in order to see this remarkable geological structure people travel a distance of some six miles.

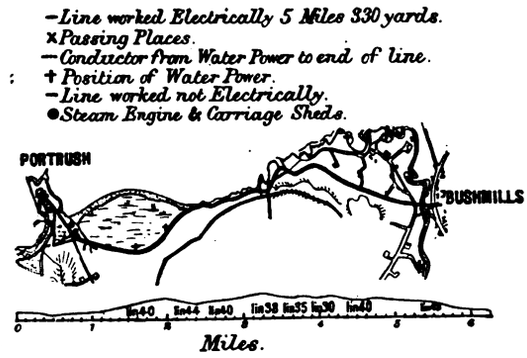

FIG. 10.

Not far from the line of route between Portrush and the Giant's Causeway is a place called Bushmills, through which a river runs, and this river has a very pretty and at the same time useful fall of water, which is utilised to work dynamos, which transmit currents of electricity through an insulated rail alongside the track of the railway to supply motive power to the cars. You now see a picture of the tramcar used (Fig. 11); that is a plan of it; the other is a perspective view; the

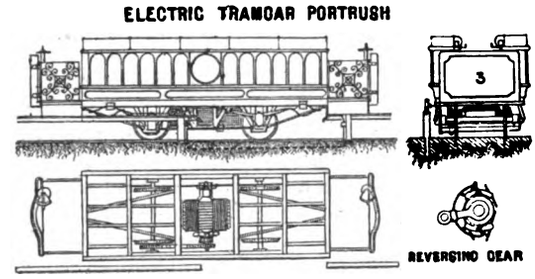

FIG. 11.

motor itself is shown in plan. You see the two electro-magnets, and the armature, or coil of wire, that rotates is in the centre. The rotation of that armature is transmitted to the wheels by

Digitized by Google

means of the chain-gearing that is shown. This railway at Portrush has been the forerunner of a great many railways in different parts of the world, but the most complete and the most perfect railway of its kind has lately been carried out by Dr. Edward Hopkinson, Sir William Siemens's assistant in carrying out the Portrush Railway. I refer to the Bessbrook and Newry Electric Railway. Instead of showing you a drawing of this railway, Dr. Hopkinson has made and sent us a model; that model is fixed to the wall of this room by five brackets, on which the rails have been placed, and a coach. A small motor is attached to the coach. When I turn on the switch, you see, away goes the car along the railway, and on getting half-way it passes a brass pillar, catches a switch, which reverses the current, causing the car to return.

I read once a rather curious paragraph in a Belfast paper about the Portrush Railway. It was supposed that persons got shocks by stepping on one rail and touching the other. The paragraph ran as follows:—"A rather mysterious affair has happened in connection with the insulated electric rail on the Giant's Causeway and Portrush Tramway. It appears that country people are in the habit of touching the rail and receiving harmless shocks, but on Thursday evening a ploughman returning with his horses, stood on the rail to mount. [Well, he could not; there was no rail to enable him to mount; the rail is on the wrong side.] Immediately on applying his hands to the horse's back, the brute fell dead against the rail. The strange part of the affair is, that the man was uninjured, although the current passed through his body to the horse." That is a sample of reliable history.

Exhibitions have been very celebrated for electric railways; there was one at Paris, another at Munich, at Vienna, Antwerp, Philadelphia, the Inventions Exhibition at South Kensington, and at Edinburgh. The one at Paris carried a great many passengers for a distance of about a third of a mile to the Electrical Exhibition there. The peculiarity of it was that the conducting wires were overhead, and the rails were not made use of as at Newry and Bessbrook.

Another application of electrical power tried at the Paris Electrical Exhibition was carried out by M. Tissandier, who attempted to navigate a balloon by its means. The balloon worked satisfactorily inside the Exhibition building, but failed when tried in the open air, being simply carried away by the air currents, having nothing for the fans to work against. A good deal more is wanted to be known before we can possibly solve the difficulty of navigating balloons, and at present we are simply dependent upon currents of air to carry us from one place to another.

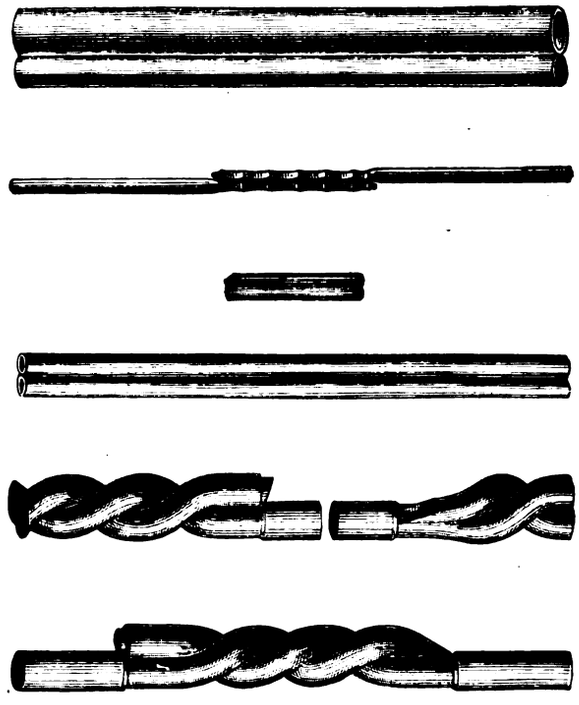
A very curious departure from the ordinary practice of conveying materials was started by Prof. Fleeming Jenkin, who is, unfortunately, now no more, and he, in conjunction with Profs. Ayrton and Perry, started a system called telpherage. Not far from Lewes, a mile or mile and a-quarter from the Glynde Railway Station, in the Downs there are certain clays which are valuable, and from the clay pits the clay is sent down to Newhaven for shipment abroad. This system of telpherage carries the clay from the pits to the station by means of electricity. Two heavy wires are fixed on cross-beams, or posts, which pass over the meadows, they do not interfere with the roads, or the grazing of cattle, they pass through bogs, marshes, rivers, and anywhere you like, and on these wire skeps—a kind of bucket—are carried on rollers, by which they pass along. Each skep carries about half a hundred weight of stuff. The arrangement is extremely ingenious, and daily and hourly trains pass by this means over the Downs to Glynde Railway Station carrying the clay. Such is the telpherage sytem.

But there is one system of carriage where electricity is destined to become more useful and more valuable than any other that I have brought before you, and that is in the working of a system of tramways in towns. There are few people who know that the number of horses required to work a tramway is 12 per car. My figures are taken from Manchester, where there is one of the best worked systems of tramways that we have in this country. There every car requires 12 horses to work it; the life of a car horse on those tramways is only four years. Working tramways in the north, wherever there are heavy gradients is really cruelty to animals. We know that a horse can only do a horse's work; there are some men who can do a good deal more than an ordinary man's work, but we rarely should expect any man to do more than five or six men's work. But these tramway horses are absolutely frequently called upon to do eight or ten times more than nature has constructed them to do, and it is no wonder that their life is so very short. This remarkable fact comes out in dealing with horses from a pure matter-of-fact point of view. If we work a tram car by electricity by means of batteries placed in the car, taking the price of horseflesh and the price of batteries per ton, the cost is exactly the same—it requires a ton and a-half of horseflesh, it requires a ton and a-half of batteries to work a car. The life, as I stated, of a car horse is four years, the life of a battery is four years. A horse will hardly do more than thirty miles a day; a battery will carry a car for sixty miles a day, and, in fact, when we remember that for the price of two horses, for the life of two horses, we can work tramcars by means of electricity, then when you think that it takes twelve horses, the mere question of £ s. d. will carry the day. There is not the slightest doubt that when the matter is properly and thoroughly worked out in a practical manner, batteries can and will work tramways, and the day is not far distant when all our tramways in and about London will be worked by means of batteries, and the poor horses relegated to duties for which they are better fitted.

(To be continued.)

MACINTYRE'S WIRE JOINTS.

The annexed illustrations represent the method of joining copper wires without the use of solder which has been introduced in America by Mr. Macintyre. It will be seen that the junction consists of a double tube of copper, the size of each tube being such as just to fit the gauge of the wire. After the two ends have been inserted the tube is forcibly rotated several times so as to force the wires into the most intimate contact. If the tube and wire be



afterwards cut across, as shown in one of the adjoining figures, the metal of the wire is often found to have flowed or welded itself into one mass with that of the tube. In the second of the above figures, which represents the joint as applied to very small wires, the sleeves are compressed by a special tool, and it is not necessary to twist them. Our illustrations, which are the exact size of the originals, are taken from some specimens brought to this country by Prof. Forbes. For joining branch wires at right angles a special T sleeve is supplied.

THE ELECTRIC LIGHTING OF EMS.

The following is from the "Abstracts of Foreign Papers, &c.," published by the Institute of Civil Engineers:—"The plant used in this installation comprises a tubular boiler of six atmospheres, with Langen's step-grate and smoke consumer; two high-pressure engines, each of 70 h.-p. actual, and three shunt-wound dynamos, each giving 80 amperes and 230 volts at 600 revolutions per minute. The dynamos are connected in parallel, and the glow-lamps are arranged on seven different branch circuits. The loss of potential in the leading wires amounts to 15 per cent. Had the lamps been on a single circuit only, the potential at the one nearest the engine-house would have been 30 volts higher than at the most distant lamp, provided all the lights were in use at the same time. The insertion of lamps varying, according to their position in the circuit, from 230 to 200 volts, would not have answered so well as the seven-circuit system. A safety-fuze, switch, and current-indicator are inserted in the main wire from the positive pole of each dynamo, and between these wires and the external circuits is a series of automatic current-regulators. The return wires are led to a commutator, each being fitted with a safety-fuze, and then connected to a separate switch in circuit with the negative poles of the dynamos, so that any circuit can be cut out at pleasure. The current-regulator comprises a small relay, the armature of which is maintained between two contacts so long as the potential remains at the proper working limit; a series of resistances connected to terminal bars, and arranged beneath an endless screw, which is supported at each end by a bearing that serves also as a spring-contact. The screw carries a slider, the motion of which along the surface of the bars increases or diminishes the resistance of the circuit. On one end of the screw are two pulleys, between which is a disc of iron forming the armature of two separate electro-magnets, so arranged that the lower half of the disc is between one pole of each magnet. The branch circuit in which each regulator is placed is so disposed that an undue rise or fall of potential moves the armature of the relay against one or other of the two contacts, and thereby brings into action one of the electro-magnets; the disc is attracted either to the right or left, and one of the two pulleys, which are kept in motion in contrary directions by means of bands from the shaft, gears with the disc, and causes it to rotate as well as the endless screw. The number of glow lamps is 883, which are divided amongst forty renters; seven arc lamps, each of 500 candle-power, are likewise worked from the same machines."

ELECTRO-DYNAMIC ROTATION BY MEANS OF ALTERNATING CURRENTS.*

Prof. Galileo Ferraris, of Turin, who, as will be remembered, was one of the first to make a strictly scientific investigation of transformers, and who has since then continued to devote attention to alternating currents, has just published the results of some experiments made with a view to produce continuous rotation by their means. The experiments are interesting, because the apparatus used was based upon an entirely new principle, which may be capable of further development. The question how to produce continuous rotation by means of alternating currents is just now occupying the minds of many electricians, because the production of an alternating-current motor would greatly increase the earning capacity of central electric light stations supplying alternating currents. Whether the apparatus devised by Prof. Ferraris, and which we are about to describe, will lead to the discovery of an alternating-current motor, is a question on which we do not pretend to prophesy; but as the principle involved may also have other applications, notably in the construction of meters for measuring the supply of electricity, we think it of sufficient importance to lay a short abstract of the investigation before our readers. The principle on which the apparatus is based is exceedingly simple, and will be understood by reference to the accompanying sketches. Let in Fig. 1 the lines O A and O B represent in direction and magnitude the strength of two magnetic-fields. The combined action of these fields on a unit pole, placed in the point O, would then be represented by the resultant O R. Instead of having two distinct fields, we have one resultant field, represented in direction and magnitude by this line. If both fields undergo periodic variations of the same period, the resultant field O R will also undergo a periodic variation, and the point R will traverse a curve, the form of which depends upon the precise manner in which the lines O A and O B change with the time.

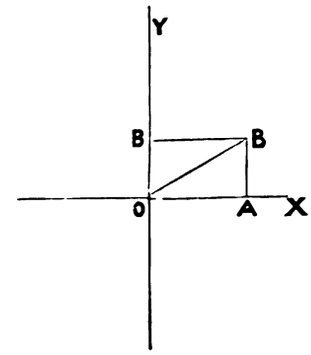

FIG. 1.

The fields O A and O B can be produced by two coils, having the lines O X and O Y respectively for their axes, and which coils are traversed by alternating currents of the same period. If the alternating currents may be expressed as sine functions of the time, and if there is an appreciable lag between the currents in the two coils, the point R describes an ellipse round O as centre. In this case the line O R representing the resultant field revolves round the centre O, the direction and magnitude of the resultant field changing at every instant. If, however, there is no lag between the two currents—that is to say, if they pass through zero simultaneously—the direction of the resultant field O R remains stationary, and the point R performs harmonic oscillation over the line R O and its prolongation with O as centre. This may

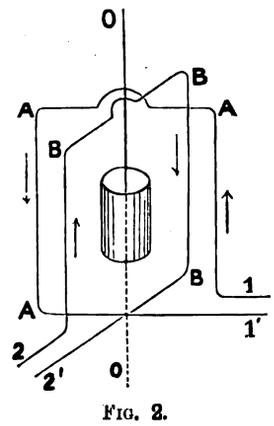

FIG. 2.

be considered as a special case of the ellipse where the latter has been flattened down to a mathematical line. Another special case occurs when the ellipse becomes a circle, and this must evidently take place when the lag between the two currents is 90°, when the coils are at right angles to each other, and when the component fields are equally strong. A metallic body suspended in the centre of the two fields, and free to revolve, must evidently have a tendency to participate in the rotation of the resultant field.

The application of this very simple principle will be clear from Fig. 2, in which the two coils are indicated by the rectangles A and B, the connections being made by the wires $1\,1^1$ and $2\,2^1$ respectively. When alternating currents are

* Abstracted from a pamphlet recently issued by Signor Ferraris. We have also availed ourselves of an excellent abstract which appeared in *Industries* of May 18th.

Digitized by Google

sent through these coils a resultant field is produced, which revolves round the line O O. In the centre between the coils is suspended a small hollow cylinder of copper, and as the lines of the resultant field cut the metal Foucault currents are induced, and by the interaction of these induced currents and the revolving field the cylinder is set in rotation. The action is exactly the reverse of that occurring in the well-known experiment in which a copper disc is rapidly revolved below a compass needle, with the result that the compass needle is deflected on account of the induced currents in the copper disc, and ultimately caused to rotate with the copper disc.

Up to the present we have spoken of two distinct currents being required in the coils A and B, one lagging behind the other by a quarter period; and to perform the experiment we might employ an alternating-current dynamo with two circuits in the armature, so arranged with regard to each other as to produce the desired lag. It is, however, possible to perform the experiment by using an ordinary alternating-current machine with only one circuit on the armature, and to produce the second current by means of a transformer. The current from the machine is sent through the primary of the transformer and then through the coil A, whilst the secondary current obtained from the transformer is sent through the coil B. It is then possible, by the interposition of a suitable inert resistance into the secondary circuit, to obtain very nearly the desired lag of 90° between the currents in the two coils. As the strength of the secondary current will, by the insertion of the resistance, be considerably reduced, it is necessary in order to obtain approximately equal fields from the two coils to employ a larger number of turns in the coil B than in A. Another method of producing the desired result consists in using a transformer with one primary and two secondary coils, and to insert into the circuit of one of the secondary coils a large self-induction, and into that of the other a large inert resistance, by which means the desired lag between the two secondary currents can also be obtained. It will be seen that in either of these ways it is possible, by means of a simple alternating current and a transformer, the coils of which are abreast, to obtain a revolving magnetic-field of approximately uniform intensity, by which phenomena can be produced in every respect similar to those obtainable from a revolving permanent steel magnet.

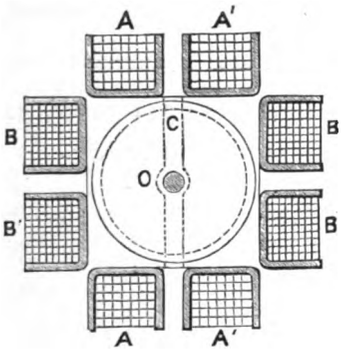

FIG. 3.

In the first experiment made by Prof. Ferraris, a Gaulard and Gibbs transformer, with an equal number of turns in the primary and secondary coils, was used. In the primary circuit was included the coil A, consisting of a few turns of stout wire, whilst in the secondary circuit were included an adjustable and non-inductive resistance and the coil B, the latter consisting of many turns of fine wire. A small hollow copper cylinder was suspended on a thread in the centre of the two coils, as shown in Fig 2. If the current was sent through only one of the coils, the cylinder remained at rest; but if currents were sent through both coils, the cylinder immediately started to revolve, twisting the thread on which it was suspended. A reversing switch was inserted in the secondary circuit, and if the current through this circuit was inverted, the cylinder was immediately brought to rest, and started in the opposite direction. Prof. Ferraris next substituted a small iron cylinder for the copper one, and found equal results; but when using an iron cylinder sufficiently large to nearly fill the place within the coils, the experiment did not succeed so well. He attributes this to the greater self-induction which the presence of iron in a large mass necessarily introduces into both circuits. Another experiment was made with a small iron cylinder, composed of a number of thin discs insulated from each other, and this experiment also succeeded. Foucault currents could not in this case be the cause of rotation, and Prof. Ferraris thinks that the rotation is due to hysteresis. A larger apparatus was then constructed, which is indicated in our sketch (Fig. 3). In this case the copper cylinder, which was mounted upon a horizontal axis in bearings, had a diameter of 3½in., and was 7in. long, its weight being 11lb. This cylinder was closely surrounded by the primary and secondary coils wound upon wooden bobbins. To make room for the shaft each coil was in halves, the primary consisting of ninety-six turns of seventy-seven mils. wire, both coupled in series, so as to produce the effect of a coil of 192 turns; the secondary consisting of 504 turns of thirty-eight mils. wire, both being coupled in parallel, so as to produce the effect of 504 turns. The resistance of the primary coils was 7·12 and 6·63 ohms respectively, and that of the two secondary coils coupled in parallel was 3·43 ohms. In the secondary circuit was also inserted a rheostat without self-induction, and the best results were obtained when the rheostat was set to between 15 and 18 ohms. A Gaulard and Gibbs transformer was used, giving eighty reversals per second. The copper cylinder began to revolve when the primary current was 5 amperes, and with higher currents the velocity could be increased to 900 revolutions per minute, and might have been still further increased but for the somewhat imperfect mechanical arrangements, which occasioned considerable vibrations. To the shaft was applied a small friction dynamometer, and the following table gives the work obtained on the brake by a primary current of nine amperes at different speeds:—

Revolutions per minute.....	262	410	516	653	722	770	900
Watts obtained on brake ...	1·32	2·12	2·65	2·77	2·55	2·40	0

The maximum energy was obtained at 650 revolutions. Beyond that speed the energy decreased, which is attributed by Prof. Ferraris to the imperfect mechanical arrangement of the apparatus, causing a considerable waste of power in vibrations. If it were not for this, the maximum energy would have been obtained at about 1,200 revolutions, whilst at 2,400 revolutions, which is the speed of the revolving resultant field, no energy at all could be obtained. Prof. Ferraris suggests that this apparatus may be used for lecture purposes, and as a motor when the power required is small, and it may also be used as an electricity meter. The torque exerted by the revolving field upon the copper cylinder is proportional to the square of the current, and in order that the total number of revolutions performed in a given time may be an indication of the number of coulombs supplied, it is necessary to introduce some opposing force which varies with the square of the velocity. If this can be done, and if the friction of the journals can be sufficiently reduced, an ordinary counter attached to the axis would indicate the quantity of electricity supplied.

ELECTRICAL COMMUNICATION ON OUR COASTS.

Mr. Robt. Bayley, of Plymouth, writes on this subject to *The Times*, as follows:—

"The Earl of Onslow has introduced a Bill into the House of Lords to give Lloyd's power to purchase land for signal stations, and thus to improve the electrical communication on our coasts. It is much to be desired that such powers may not be granted without a full inquiry by a committee into the whole question of electrical communication around our coasts, which has never been hitherto made. Last year a Board of Trade committee sat, but their inquiries were strictly confined to electrical communication with lightships and with rock lighthouses. Beginning at the most difficult and costly end of the question, and without inquiry as to the necessary for electrical communication with coastguard stations, lifeboat stations, shore lighthouses, and the salient points on our coasts, they recommend an adjournment for eighteen months,

Digitized by Google

during further experiments, which are being conducted at the Sunk Lightship only.

"We are becoming alive to the fact that our defences are not what they should be, and that our navy should be strengthened, yet this Bill, if it is allowed to pass, will leave the question of a national system of electrical communication around our coasts untouched.

"Except at a few points it is impossible to signal on our coasts at all, these points being chiefly in the hands of Lloyd's.

"Although our coasts are patrolled by coastguards, all men of the Royal Navy, Her Majesty's Navy has no means of conveying or receiving any intelligence from them—in the event of war, a matter of the first importance as regards our coast defence, which would have to be provided in haste.

"We have only to go to Denmark to find that electrical communication of the best kind has been provided by the Government on the west coast of Jutland, and, in the Kattegat, telephone lines are laid to the lifeboat and rocket stations, which connect them with the inland telegraph stations. The telephone stations are served by the man or woman who may be on the station, and they are allowed to charge about 3½d. for each message or telegram sent off. For those received no charge is made.

"The lines are laid chiefly in the interests of the fishermen, and, as they serve both lifeboat and telephone stations, they use them very freely among themselves for market purposes, as well as in case of shipwreck and for private information.

"In the year 1887 the following messages were received and sent from the telephone stations:—Received from Denmark 2,560 messages; received from abroad, 619 messages; sent off to Denmark 3,162 messages; sent off to abroad, 1,314 messages; 1,807 communications were also held between the various stations.

"At the Skaw, Hirtshalls, and the Hirtsholm lighthouses the keepers act as telegraph clerks. They advise the Copenhagen exchange of all ships that signal as they pass, and report information about weather, wind, shipwrecks, &c., to those who desire to know.

"If it is possible to have such information in Jutland, how much more should it be afforded along the coasts of this country, particularly in the English Channel, where the traffic is so great and shipwrecks frequently occur, besides the advantage of being able to signal the state of wind and weather, the passing of ships, the movements of great shoals of fish, and of the enemy. The system should be national, as in Denmark, and in the hands of the Post Office authorities. The beginning should be made at the most salient and practicable points on our coasts, including shore lighthouses, Coastguard stations, and lifeboat stations.

"It will be a matter for regret should Parliament pass the Bill now in the House of Lords in the interests of Lloyd's, without the fullest inquiry by a committee being made into the subject."

MAGNETIC LAG.*

BY MR. T. BLAKESLEY.

As mentioned in our last issue, a Paper was read by Mr. T. Blakesley, at the last meeting of the Physical Society, on "Magnetic Lag, and the Loss of Power accompanying the Reversal of Polarity in an Iron Core subject to the Influence of Harmonic Currents." On other occasions Mr. Blakesley has given formulæ for determining the lag in transformers, and for calculating the loss of work incidental to it; but in this Paper the methods of calculation were for the first time given. A dynamometer is placed in each circuit, and a third has one of its coils in each circuit. These furnish without difficulty the current, and therefore the magnetising stress produced thereby in each coil, and the angle of phase difference between them. The resultant magnetising stress is therefore known, and the phase relatively to each component. If this resultant is in quadrature with the current in the secondary, there can be no magnetic lag, for the magnetism must be in quadrature with that current. But experiment shows that the magnetic stress is in advance of the magnetism from 5° to 6°. If this angle of advance be represented by ϕ, then—

$$\tan\phi = \frac{\frac{m}{n}\,C a_3 - B a_2}{\frac{m}{n}\sqrt{A B a_1 a_2 - C^2 a_3^2}}$$

where m = the number of turns of wire on the primary coil; n = the number of turns of wire on the secondary coil; A B C are the dynamometer constants; and a_1 a_2 a_3 are the dynamometer readings.

The dynamometer constant is that number which, multiplied by the reading, will give half the square of the maximum value of the current. Thus the existence of a magnetic lag may be detected by the use of the second and third dynamometers alone, and measured by means of the three together. Further, as the current induced in the secondary coil is known, the E.M.F. of this induction can be easily calculated if the resistance r_2 in that coil is also known. This E.M.F. per turn is $\frac{I_2 r_2}{n}$, I_2 being the secondary current. But this must also apply to the coils of the primary. Therefore, $\frac{m}{n} I_2 r_2$ is the whole induced E.M.F. in the primary, and $\frac{m}{n}\frac{I_2 r_2}{r_1}$ must be the induced component of the current in the primary coil; and, consequently, $\frac{m^2}{n}\frac{I_2 r_2}{r_1}$ is the magnetic stress arising from it, and forms one of the components of the whole magnetic stress due to the current in the primary coil. Their difference of phase being known, the remaining component due to the E.M.F. (E) of the machine itself, viz., $\frac{E}{r_1} m$ becomes known.

All these vectorial quantities can be plotted geometrically in a way with which Mr. Blakesley has endeavoured in other Papers to make electricians familiar, so that the work done and other matters become functions of a simple triangulation, the sides of which merely involve dynamometer readings and constants, the resistance in the circuits, and the number of turns of wire in the two coils. The whole work done by the machine takes the simple form—

$$r_1 A a_1 + r_2 \frac{m}{n} C a_3.$$

The first term is obviously the power heating the primary coil. The second term is the sum of the power heating the secondary coil $r_2 B a_2$, and the power involved in the magnetic reversals; it follows that the latter is equal to

$$r_2\left(\frac{m}{n} C a_3 - B a_2\right),$$

which contains as a factor the numerator of the expression for the tangent of the lag, and showing that one is the result of the other.

In speculating upon the cause of the lag Mr. Blakesley believes that the increasing magnetisation calls into being an opposing magnetic stress, as motion in a medium calls into being an opposing friction. This induced magnetic stress must be compounded with those impressed by the currents to obtain the effective magnetic stress which is in phase with the magnetism. This involves the conception of magnetic self-induction and a corresponding coefficient symbolised by N, to which Mr. Blakesley is careful not to attribute constancy, though he points out that its constancy is a necessary condition to the maintenance of the harmonic character of the changes. These views were illustrated by experimental results.

* Abstract of Paper read before the Physical Society on May 12.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the meeting on Thursday, 17th inst., Dr J. Hopkinson, F.R.S., in the chair, it was announced that the Council had decided that, in the discussion of Papers read before the Society, speakers should be limited to ten minutes each. At the end of eight minutes a bell would be rung, and if the speaker did not conclude his remarks within the two minutes succeeding, the chairman should put it to the house whether he be allowed to proceed. The consideration of Mr. Crompton's Paper was then resumed.

Central Station Lighting.—Transformers v. Accumulators.

The CHAIRMAN called upon Mr. Crompton to reply to the discussion on his Paper, a report of which has already appeared in former issues of *The Electrician*.*

Mr. CROMPTON, in reply, said: The long discussion which has taken place on my Paper, and partly in my absence, is not a very easy one to answer without extending my remarks to a troublesome length; but I will do my best, by grouping them into various heads and by giving one answer for all such remarks as may be thus grouped. I must at once make an explanation regarding Mr. Hammond. Mr. Hammond seems to labour under the idea that when I spoke of some installations of his I spoke of them as installations carried out partly for advertising purposes. Nothing was further from my thoughts. I spoke of them as pioneer installations—as installations more for the purpose of popularising the electric light than being specimens of what installations of a more permanent nature ought to be; and I characterised all overhead installations thus. I must apologise to him at once for the mistake I made about Eastbourne. A further misunderstanding has taken place between Prof. Forbes and myself.

He appears to think that I was discussing the question of transformers *v.* accumulators for all purposes and for all kinds of installations. That was not the object of my Paper. My Paper was to discuss transformers *v.* accumulators under the light of a certain installation which I described as suitable for London; and I commenced by saying that I put overhead wiring out of court. Wherever overhead wiring can be used I have no doubt that distribution by means of alternating currents and transformers is a very good system to use, and probably is considerably cheaper than that by batteries. But I wish to confine the discussion to the limits I put upon it—that is, the lighting of London. I will now go on to the remarks that were made by Mr. Kapp. Mr. Kapp commenced with a discussion of my load diagram. Mr. Kapp stated that though no doubt my load diagram was correct, it was hardly a representative one for London. He stated that if I had taken a district in which there was much office lighting, my valleys would have been filled up, and that instead of the 2,100 units calculated from the area of that diagram, I should get the 3,600 units which he spoke of in his article published in *Industries* on December 2nd. Now, I do not admit this for one moment. London is not like New York. In London our residential districts contain very few offices. Our offices are grouped together in the City—a few are at the West End, but the majority are in the City. No doubt a diagram prepared from the City of London would be widely different from the diagram I have shown on the wall; but I think you, all of you, will admit that the matter that is of supreme interest at the present moment is the lighting of our private houses in London—the houses in which we live. It is there that we shall feel the full benefit of the electric light, and anything that any of us can do or say which will forward the cause of the distribution of the electric light into our private houses is of the utmost value to all Londoners at the present moment. I will go on further to say, while on the subject of these diagrams, that I admit the full force of what Sir David Salomons and several other speakers have said on the subject of the sale of motive power. There is no doubt that the sale of motive power is much to be desired, as by such sale we shall get a filling-up of that valley which will be of the greatest advantage to the supplying company. For, mark you, as the capital expenditure of the company is somewhere in proportion to the height of the peak of the diagram, and the income of the company is in proportion to the area of the diagram, it follows that the more we fill up the valleys the better the company will pay (hear, hear). Now, this filling-up by the use of motive power of course is a thing to be devoutly desired, and I hope it will come. But I hardly think it was a fair argument for me to use in favour of the accumulator—the B.T. system as against the A.T. system, which cannot use motive power, and I think you will appreciate my motives in keeping it on one side. But if I did wrong, I did it simply from the motive of absolute fairness (hear, hear). Every argument that I have been using in favour of the B.T. system will be considerably strengthened when I have the additional income that I shall get in the day time from motive power by using the direct system and the batteries. Mr. Kapp, I am sorry to say, appears to have misunderstood my figures in Table I., because otherwise it is difficult for me to follow the calculations that he made. He says that, instead of using the cable that I used, costing about £116 per hundred yards—that is to say, for the double cable—he proposed to use cables insulated in the same manner, but covered with lead, bringing the price up to £130. He hopes by that extra expenditure on the cable itself to save a great deal of money in the cost of laying. Well, in this he will find himself mistaken. He seems to think that the sum of 3*s.* per yard is an ample sum to cover all the expenses of laying a pair of cables under a London footway. Is he aware that the figure that I have put at £25 per hundred yards for trenching and replacing is absolutely the figure levied by the Vestry? That is to say, for every yard of York paving we take up we have to pay 4s. a yard, for every yard of asphalte 11s.; for wood pavement about the same as asphalte. If we suppose there is only about 10 per cent. of asphalte footway in our lighting we must fetch up the 4s. to 5s., and I have taken it at 5*s.* throughout, which gives the £25. Further than this, Mr. Kapp seems to have made the most astonishing omission. He seems to think that contractors will be found who will lay cables without taking any profit, and this notwithstanding the risks attendant on the work. I put a sum down for that, and I think that you will all admit that it is a very small sum when you consider that it has to cover the expense of drawings and the expense of the clerk of the works and the engineer's fees who devises and manages the installation. If you thus correct Mr. Kapp's estimate it comes to a figure sensibly higher than mine—viz., £187. 10s. per hundred yards. That is a specimen of Mr. Kapp's criticisms of my figures. It is highly important that I should dwell upon this point, because I should tell you that, on this cost of laying the mains, so much depends. It is the one item that has been very little understood, for the simple reason that none of us have had any experience of it until the last two years, and I really thought that I was bringing before you something that would be of very great use to the members. Referring to my second table, General Webber, although he criticised it tolerably severely, yet the edge of his criticism is taken off by the fact that he misunderstood it. He talked of the conductor being suspended from the roof of the culvert. If that were the case, no doubt water collecting on the roof would run down the suspending loops, whatever they are made of, and would deposit a film of water, which would stand on the insulators and very much reduce the insulation. But, as a matter of fact, it is not so. The insulators stand upon short pillars from the bottom of the trench, and I see no reason to believe that the insulation would suffer in any way if we had had a couple of inches or even more water, either running or lying in the bottom of the trench throughout its length. How it is possible for the state of things proposed by General Webber to occur I cannot conceive. He says we shall gradually get the trench blocked up by the *détris* left by water, that vermin of every kind will congregate in the trench, and we should have legions of rats running along them, and in a short time we should lose the insulation entirely. Well, we have had one year's experience of this class of culvert, and none of these things occurred. Not only have they not occurred, but there is no sign of them occurring. We have had a very trying winter. As is natural under the circumstances of commencing a new installation, the trenches have been opened many times oftener than they will be in the future. They have been exposed to all kinds of weather. There have been far more opportunities of wet getting into them than there ever will be again, and yet, in spite of that, the insulation of these cables is as high, length for length, as that of the best cables made in the world, which, I believe, are made in London or near London (hear, hear). Well, on this point I want to bring to your notice an interesting fact, which I think may be also of some use to you. It is very easy to get high insulation in a cable that is not cut into by the distribution branches being jointed on to it. As long as the insulating covering of a cable remains intact from end to end it is very easy to measure its insulation by megohms, but when there have been a few hundred cuts made through the insulation, and the branch wires have been jointed on, it matters not how carefully the insulation is replaced and the joint remade, every one of those joints becomes a source of leakage. The megohm resistance goes down very soon to a few thousand ohms, and, what is a most curious thing, the whole of the exterior surface of the cable becomes a means of communicating the leaks that start in the minute cracks at the joints to the ground—that is to say, there is an enormous ground surface wherever hemp or jute covering comes in contact with the pipes or troughs containing the cables. I am speaking now from practice. I find it extremely difficult to make these joints tight, and it is *the one* point where underground cables carrying these high potentials proposed by the advocates of the A.T. system will find their greatest difficulty. There has been a writer in one of the electrical papers, I forget which, who calls attention to this fact, and I am sure that whoever plans a district and carries out a district with this large number of attachments to the high-tension mains will find his difficulties at these points are extremely great, infinitely more than any difficulties we are likely to encounter with the B T system. I am perfectly aware, that there are many places in which one cannot use the culvert system, as has been stated by Mr. Fleetwood. But Mr. Fleetwood has made a mistake. He believes that it is necessary to have a culvert 18in. square. We have actually used culverts only 5in. deep, and, I believe, 4in. deep in some cases. We want a considerable width, because it is my system to put a mid feather between the brickwork and every one of my conductors, so as to make it impossible for any swinging or side movement of the conductor to make a short-circuit. But 18 inches is found ample for the three-wire system, and I have no doubt that, if I want to get a four-wire system, 24in. would be ample. There is no difficulty in getting width under the footway, the difficulty is in getting depth. Hitherto we have been able to get a sufficient space in depth. We have, in several cases, had the depth cut down to 2in., and then no system will do but putting in lead pipes and drawing separate cables into them. I mean the ordinary plumber's lead pipe of an inch and a-half to two inches diameter, and drawing the cable into that.

I must turn now to the cost of the generating plant. Most of the actual makers of alternate-current dynamo machines appear to think that I have under-estimated their cost in my Paper. Prof. Forbes is alone in thinking the contrary; but this is no doubt due to the wonderful organisation of Mr. Westinghouse's factory, who, as he says, makes only three patterns of machines, and has, consequently been able to turn them out by special machinery. There is no reason why we should not be able to imitate this in this country, if we have a demand equal to that of Messrs. Westinghouse. But, if my arguments are correct, I do not think there will be ever the same demand for alternating sets in this country that there will be in America. As to the cost of transformers Mr. Kapp says I over-estimated them, not because he considers that my price is too high, but because I use too many of them. I have estimated the cost of fixing a transformer common to two houses at, I think, £15, which price includes the chamber which contains it, and all the labour incidental to fixing; but he thinks that the number of transformers could be reduced, and he at once goes to the extreme of collecting his transformers into ten distributing stations. Now, I wish to point out that, if we take Mr. Kapp's figures as correct, to distribute over these ten stations he will use just as much copper as I use also for distributing from 4 stations. He told me my calculations were all wrong for 4 stations, and that the copper I had allowed was only sufficient to give the correct fall of potential if I distributed from the ten stations. Therefore, he will have to adopt my figures, and he will have to adopt 20,000 yards of cable at the cost in my table for the B.T. system. By that means he will at once put £6,000 on the top of his distributing mains, and, on the top of that, he will have to add the cost of such sub-feed mains as he employs to carry the current from the end of his large charging mains to these sub-stations. I have not worked that figure out because I do not know how he is going to place his station, but it will probably add another £3,000 or £4,000; so we have to add £10,000 on to the cost of his system at once by this new method of distribution. What is he going to gain by it? He is going to gain a few thousand pounds on the cost of transformers. Possibly he may. I have given the total cost of the transformers there as £7,500. He may gain one-half of that; so that to gain £3,500 he is deliberately going to sacrifice £10,000. That is a specimen of the proposal made by Mr. Kapp to reduce the cost of the A.T. system. I have, however, from conversations I have had with other gentlemen, learned that Mr. Kapp's proposals are not generally acceptable. From what I understand from Prof. Forbes's remarks, and from other gentlemen's remarks, it is pretty certain that they would wish to put transformers to one or two houses as I have put them down; and, under those circumstances, I do not see how the cost can be reduced. It is not

Digitized by Google

the cost of the transformers themselves, but the cost of starting a fresh job each time that you put down a transformer, and these will not be all put down simultaneously. A couple of men will have to be sent out, and we all know, at least all we contractors know, how much more expensive is a small job of that kind than the continuous work that you can give out on contract. I think those of you who have had experience of working in the streets will admit that the figure of £15 for every two houses, including the cost of the transformer itself, including the profits and risks of it, is exceedingly small, so that I do not see how by hook or by crook that cost can be materially reduced.

I now come to the very vexed question of the efficiency of these transformers. My statement that their efficiency is very low at low rates of output has been traversed by several speakers. Mr. Mordey wrote to me on the subject, as he was unable to speak during the discussion. I am quite prepared to say at once that I will adopt the figures given by the advocates of the alternating-transformer system, I will suppose that the efficiency is as high as they make it to be; but what I did say in the body of my Paper, and what I now say is, that 40 per cent. of the total output of the station is taken at extremely low rates. You will see what 40 per cent. consists of on that diagram, you will see that it hardly goes up to the lower horizontal line, and that really means that there are two or three lamps running in each house during about nine hours of the day. Two houses having one transformer common to both would require this to be of 4,800 watts capacity to supply their maximum demand, whereas during these nine hours it would be worked at about 108 watts capacity—that is, rather less than four per cent. of its total output, and it is during this time that its efficiency is so very low, and, what is more, it is during the corresponding time that the efficiency of the accumulators is at its highest.

I have got to the point at which I must cordially endorse all that Mr. Preece has said when describing the pluck and perseverance shown by Messrs. Gaulard and Gibbs. Nobody admires the results of their labours in pushing the system to its present success more than I have done. Nothing in my Paper was intended to detract from the credit and honour they have won, in the teeth of just such uncompromising opposition as I am now receiving from their friends (laughter). Mr. Swinburne made a remark about transformers which does not appear to have been noticed by the friends of the A.T. system. He points out that the transformers do not regulate—that is to say, to use our electrical slang expression, they compound down; the E.M.F. falls as the load is increased, and no one has succeeded in winding them so as to overcome this difficulty. If this is so, and no one has denied it, it is another serious difficulty in the face of the distribution by the A.T. system.

Now, I turn to the accumulators. First, I must point out generally that my Paper speaks solely of the use of accumulators as transformers. Mr. Drake appears to be the only gentleman who has brought this strongly before your notice. There is a very wide difference between accumulators worked in the manner that I have described, so that during the hours of large demand most of the current comes direct from the dynamos—the accumulators only supplying a portion of the current during the peak of the diagram, and again supplying the current during the very long periods of small output—and the other plan of using accumulators, which is to fill them in the daytime and discharge them at night. Mr. Frank King, Mr. Parker, and other gentlemen asked me why I did not refer to the Colchester installation. Now, I admit that the Colchester installation was worthy to be referred to; but it is so totally different from the system that I have been talking about, and it is so utterly impossible to compare its cost with the alternate transformer cost, that it is out of court. These gentlemen do not appear to see that you require six times the amount of batteries—so that my figure for batteries must be multiplied by six if you are to use them in the way they were used at Colchester—and the mere fact of the cost of those batteries makes the capital charge so high as to rule them out of court. You see, after all, I am a very timid user of batteries. I do not deny at all that we are only just beginning to understand them; and no doubt, as our experience extends, I should use them much more largely than I now propose.

The next point I wish to come to is that I have been asked why I stick to the figure of 400 or 450 volts as my figure for distribution. The reason I do so is that, although I would very much like to use 600 or 800 volts, I do not know whether difficulties will then occur which we have not hitherto met with. I have successfully distributed an installation of 13,000 lights at Vienna—that is the size of the Vienna installation. It is larger than this installation we are talking of now. The mains are nearly 1,500 yards long; consequently, it is very much on all fours with the installation described, and it is not too much to say that everything that I have put down both for working cost and capital cost in my tables is nothing more nor less than the figures from Vienna as near as I dare state them. At Vienna the 440 volts we are using has never given any trouble.

The Le Mans station, about which I have said very little, is an extremely perfect little station, which has worked from the commencement up to date without any hitch of any kind. At the gasworks there is a generating plant, working at 250 volts. A pair of cables is carried to an accumulator station close to the market place, and from thence the three-wire system is taken all over the town—at least a modified system, for with batteries you do not require quite the same complication as when you are using dynamos working a three-wire system. You, gentlemen, hardly appear to appreciate the fact that when you are using batteries—even on the direct system—you may reduce the cost of your charging or feeding mains very largely if you put your batteries at the distant point. You make a corresponding gain when you use the three-wire system and put the batteries again at a distant point, and you make still a corresponding gain again with the five wires, or four batteries in series, with the batteries at a distant point. I have shown that the gain is then so great that when you are using the 440 effective volts which the extra cost of the copper involved, as against the 2,000 of the other system, is more than compensated for by the extra cost of the insulation of the wire of the mains of the A.T. system. Thus you see, if you compare one main with the other, the figures are very nearly alike. In the case of the A.T. system, the cost is £6,160 for 2,000yds., and in the other case it costs £6,137. I do not deny for a moment that when the length of the charging mains gets beyond 2,000yds. there will be a considerable balance in favour of the A.T. system.

As to Mr. Kapp's criticisms on the cost of accumulators, you will notice that his questions have been answered by all the practical makers of accumulators. Mr. Parker, Mr. Sellon and Mr. Drake have agreed that my figures are correct. Now as to the efficiency of accumulators, about which so much has been said. Mr. Preece, Prof. Forbes and a great many other gentlemen seem to be surprised that I claim an 80 per cent. efficiency between the lamps and the terminals of the dynamo. I may call attention to this fact strongly later on. But in reply to this I may state that I have obtained this efficiency for many months at Vienna, using E.P.S. accumulators. I have obtained a far higher efficiency at Kensington and in a private installation of my own. I am speaking now of the watt efficiency. I say that when the dynamos and batteries are worked in parallel, and the current has neither been taken out nor put into the accumulators, there is little or no loss, due to the fact that the batteries are connected parallel to the circuit, which otherwise is a direct circuit. Of course if there were any short-circuits in the cells, or any leakage inside them from plate to plate, then there would be loss. But it is perfectly easy to guard against such a thing happening, and with proper precautions it need not happen. It has not happened in Vienna, and it has not happened in Kensington. Now I have shown that at the time when there is about 60 per cent. of the total output the efficiency of the accumulators does not come into the question. It is, then, a mere question of direct supply. I have shown you when speaking of the transformers that for nine hours the batteries are discharging at a very low rate. From actual experiment I know that you can get an 82 per cent. efficiency during this time, but I do not claim it. I have really only calculated 70 per cent. Now, if you add 60 per cent. of the output at no loss, and 40 per cent. at the loss I speak of, you get a total efficiency of 87 per cent, whereas I have not claimed anything of the kind. I have claimed something very considerably less; therefore the severe criticisms Prof. Forbes has cast on that portion of the Paper entirely fall to the ground because he has not appreciated these points.

I turn now to the question of the depreciation of batteries. Mr. Gordon has made public certain figures which show without any further comment from me what is my personal opinion, and the opinion of my partners and those working with me, as to what we can afford in the way of maintaining accumulators. I think we have made ourselves safe on that contract that he read out to you. It was not my intention that he should read it out, but as he has done it, it is there for you to judge of. All the experience I have had with the form of accumulators that I have been using points out that we are well within the mark when we say that we can maintain the 12½ per cent. I think I am at liberty to say this much, that during my recent visit to Vienna, which is since the Paper was read, I took very great pains to inspect the large battery of accumulators. I ascertained that the company were not willing to allow anybody to contract and maintain the accumulators at 10 per cent They thought they could do it for considerably less (applause). I believe at Kensington Court the cost of the battery, of the alterations and little repairs that have been made to the battery during the fifteen months' working, amounts to about 2 per cent. of its cost. Mr. Kapp bases certain elaborate calculations on Mr. Shoolbred's mains at Bradford. Mr. Shoolbred, on the contrary, tells me there were no calculations made for Bradford.

Mr. KAPP: I made a calculation quite privately when I saw the matter at Bradford, and that was the result.

Mr. SHOOLBRED: I beg Mr. Crompton's pardon. I never made any such statement. I cannot understand what he means.

Mr. CROMPTON: I understood decidedly that you did not know how many lamps were going to be used in Bradford, and that the cables were to be laid down as they were required.

Mr. SHOOLBRED: It is not an installation for lamps; but you said there were no calculations made whatever, which is a very wide statement, as if it was a haphazard laying down altogether.

Mr. CROMPTON: I now come to the remarks of Mr. Hammond. When Mr. Hammond tells me that he thinks there is no necessity for providing accumulators, because, of course, everybody knows when the steam engine is going to stop, all I can say is that Mr. Hammond's experience has been exceptionally favourable. But what about the belt coming off? Has nobody had a belt off? And what happens then? What happens if you have got four or five machines parallel and the belt comes off one of them and the other machines have to drive?

Mr. MORDEY: The cut-out acts then (laughter).

Mr. CROMPTON: A gentlemen says a cut-out acts. I know what happens in addition—a report comes in from the customers next day that the light has been exceedingly bad on the previous evening (laughter). On the other hand, with accumulators you can stop the engines for half an hour, as was the case when we had not boiler power enough at Kensington. We were able to stop the engines and get up steam and start them again without the customers knowing anything about it (applause).

Prof. Forbes has certainly made a mistake with regard to the efficiency of the Westinghouse plant He does not seriously believe you can get 600 kilowatts out of 1,000 horse-power. He will, no doubt, have to admit that he wants about 1,200 horse-power to get the 600 kilowatts, and he will have to admit that the 250 horse-power I have allowed for reserve power is not an extravagant figure, but is the very smallest that is necessary. When he has admitted that he has got to admit the extra allowance for increased cost of site and building, and when he has admitted those two items he has admitted pretty nearly all

Digitized by Google

that there is in my Paper, excepting that of the cost of the mains; and I decline to discuss the mains with him, because he bases everything on overhead wiring, and mine is underground wiring. I think I have answered most of the speakers who have discussed my Paper. The opinions of those who are practically connected with the working of central stations are practically fairly balanced; but figures are worth more than opinion. There are, no doubt, several persons in this room who know that I speak accurately when I state that the experience of the Grosvenor Gallery installation is such that the estimate for the future coal consumption is based on the supposition that each electrical horse-power in the lamps will take about 18lb. of coal. It is needless to say that I should not have the hardihood to stand before you if I thought the B.T. system would take so much as that, or that it would take a quarter as much. I hope to have an opportunity at no distant date of proving this question beyond dispute. I do not know whether the Grosvenor Gallery people will give you an equal chance as I intend to do, for as soon as our enlarged plant is in at Kensington I shall have great pleasure in allowing gentlemen to make such experiments as they choose to show that what I have stated about the consumption of fuel on the B.T. system is correct.

I have shown that in the A.T. system the dynamos are slightly more expensive; they are certainly more difficult to put parallel. In the A.T. system a part at least of the machinery must always be in motion; whereas with the B.T. system you have got smaller plant, you have got cheaper plant, you have got machinery which need not be always moving, and consequently the labour in the B.T. system costs much less than the labour in the A.T. system. I have shown that the saving in conductors in the A.T. system is excessively small, whereas the likelihood of the breakdown of underground conductors when they are used in the A.T. system is much larger than in the other case. I have shown you that there is no motive power possible with the A.T. system. I have shown you that the A.T. system is extravagant in fuel, and that the B.T. system is not so (oh, oh). I think that when I have put all this together that I have prepared a very formidable array of charges against the A.T. system.

On the motion of the CHAIRMAN, a cordial vote of thanks was then awarded by acclamation to Mr. Crompton for his Paper, and for his reply to the discussion.

"On the Risks of Fire Incidental to Electric Lighting."

On resuming the discussion on Mr. Preece's Paper,

Mr. HEAPHY said that he had obtained permission to make a statement that evening as to the reasons of the committee on the Phœnix Rules being interrupted. But in the account given by Mr. Preece, he unintentionally conveyed an erroneous impression. Had it not been for that remark he (the speaker) should not have spoken at all, for obvious reasons. In May last the committee of the Council was formed to revise their rules of 1883. Communications were opened with the Phœnix on the matter, the result being that a tentative agreement was arrived at that in order to settle once for all any additions as to the rules for the future the Telegraph Engineers' Rules and the Phœnix Rules should come out under the same cover, the cover to contain no mention of the Phœnix. The first portion of the pamphlet was to contain the general rules and principles for installations drawn up by the committee. The second portion of the pamphlet contained "The Phœnix Detailed Rules for Installations," that being the acknowledgement that these detailed rules were the Phœnix Rules. In order to make certain that there was nothing in the Phœnix Rules objectionable the committee were to form a sub-committee to go over them clause by clause and word for word, and in the event of their not agreeing the arrangement was to come to an end. These gentlemen were to be men practically acquainted with the difficulties of electric light installations, viz., Mr. Preece, Mr. Siemens, Mr. Crompton, and General Webber. There were many sittings at the offices of the Telegraph-Engineers, and there was not the slightest hitch or difficulty of any kind, and the Phœnix Rules were unanimously approved of. After certain verbal alterations had been made, and a few other slight variations (all of which were agreed to), an acknowledgment clause was then framed and agreed to. The sub-committee then revised their general rules. With those he had nothing to do. The rules came out in the cover of the Telegraph-Engineers, and that was done to prevent the susceptibility of any other fire office which did not like the word "Phœnix" to be alluded to. They were to see the "Society of Telegraph-Engineers and Electricians' Rules and Regulations recommended for the fire risks from electric lighting." Then came the names of the members of the committee, with Mr. Preece as chairman. Then there was a little acknowledgment clause, as follows:—"The following detailed rules having been laid before the Society for approval are recommended for general use." He thought that the matter was at an end so far as he was concerned, when he received a letter to attend their committee to explain certain rules. He thought that this was strange, as the matter had been so thoroughly thrashed out by the sub-committee, and that they were so thoroughly conversant on every point. However, he accordingly went, when, to his surprise, the first thing he heard spoken at the table was that the acknowledgment clause was called into question, with a kind of half intimation that instead of the detailed rules being acknowledged as the Phœnix Rules they should be called rules based on the Phœnix. He also found that the whole of the Phœnix Rules were to be gone over again—not the original Phœnix Rules, but the slightly altered Phœnix Rules. That was the point. They were under the cover of the Telegraph-Engineers (laughter). What, then, was the position of the Phœnix Fire Office? These rules might have been slightly altered again verbally, and the acknowledgment clause altered objectionably, and all copyright lost; perhaps the very name of the Phœnix might have been expunged in the next edition, and what remedy would the Phœnix have had? None whatever. If it had been objected to the answer might have been the detailed rules had been drawn up with the consent of their own representative sitting as one of the committee; they could not now refuse to recognise nor object to the acknowledgment clause, whatever it might be. The Phœnix Fire Office, after a time, might have been deprived of its rules. Well, what was the only course open to the Phœnix? What would any of them under the circumstances have done, except to retire from all negotiation? He had to acknowledge in high terms of praise the conduct of Mr. Preece, Mr. Crompton, General Webber, and Mr. Siemens; and he could not tell them the amount of time and trouble those gentlemen had taken, and this difficulty would not have arisen had it not been that these people were outvoted by the others.

Mr. PREECE: I object to that.

Mr. HEAPHY: Well, they were outvoted. He thought he had the sympathy of practical men. He wrote a letter to the committee, and at their next meeting they declined to give him any information as to the acknowledgment clause, whether it was to be altered or what was to be done; and until the sittings on the Phœnix Rules in the pamphlet—not the real Phœnix Rules - had been completed he had nothing to do but retire. Several gentlemen of the committee asked him to stop, saying that he could reckon on their support; but when he said they might be outvoted by others of a different opinion the reply of the others was, "Yes; that might be so" (laughter). He did not wish for a moment to imply that that committee would have done anything that it did not consider right and honourable. He did not wish to cast the slightest imputation upon anyone; but they must remember that there were often two ways of regarding the same thing, and what would seem perfectly fair and right in one view would be felt as a bitter wrong and injustice from another point of view. For instance, the speaker last Thursday actually stated in effect that, because some of the clauses in the Phœnix Rules which were brought out in February, 1882, were then similar to certain rules in America, therefore there was no right to copyright in the present Phœnix Rules, and that, too, notwithstanding all the original thought and labour bestowed on them to make them perfect, and that they were tried upon systems of lighting undreamt of six years ago. The Phœnix Fire Office was anxious to do everything that was just and right. He would just tell them what had taken place connected with the use of their rules by one of the leading offices of the day. The Phœnix gave up everything; the only thing was to have that acknowledgment clause to save their copyright. "The following rules"—that was the only acknowledgment, the only page in which the Phœnix name was mentioned. "The following rules having been drawn up by the Phœnix Fire Office for electric lighting installations and electric power installations, have been adopted by the leading fire offices throughout the kingdom, and are recommended for general use." He could assure them that demand for these rules from a number of offices was getting so large that it was becoming difficult to supply them in time. He believed almost every office in the kingdom would have used them with certain exceptions; but one office came and said, "You must not say the 'fire office rules'—you have no right to say 'fire office rules'"—or words to that effect. And something to this effect, "You say they have been adopted by the leading fire offices throughout the kingdom, but we are not aware that all the leading offices *have* agreed." And so they agreed to withdraw that part of it. Now he left the meeting to judge of the feeling in that matter. It did not seem to matter what trouble the trade had been put to as long as the "Phœnix" was put away. The meeting knew what injustice was, for they had had to feel the tyranny of Chamberlain's Act; but that Act was mercy itself compared to the one which was now sought to be imposed upon the Phœnix. They had had 21 years allowed them before their worst time would come (laughter), but he was not to have 21 weeks. He never believed that the meeting would be a party to such an injustice (cheers).

Mr. HUMAN (of the Guardian Office) said he had risen to refer to the last occasion, when Mr. Preece rather condemned a clause which applied in his (the speaker's) opinion to another purpose, and which had another application altogether. Mr. Preece read out the clause of those rules which specified the minimum electrical resistance of the insulated covering to the conductor; and he compared that with the Society's rule which dealt with the total of leakage of an installation. Now the two things were not altogether the same, and they did not deal, as a matter of fact, with the total leakage. First of all, in the previous rule, they specified what materials should be used to form the coating of a conductor, and then with reference to that they felt that it was necessary to specify what should be its minimum electrical resistance, and they adopted simply what was the common practice of the trade. He believed it was a practical rule of the makers of conductors—they specified so many megohms resistance; and they believed that it was a term that was well understood by those dealing with insulated conductors. It was of very simple form, and he did not quite understand why Mr. Preece condemned it.

The EARL of CRAWFORD and BALCARRES said: Before this discussion closed he wished to say a word as to the question of the rules that were put up for the guidance of electric contractors in wiring houses. A short time ago he had the honour of being admitted to the committee appointed by this Society to consider the rules, and he then spoke to them, urging them not to go into this question of the multiplication of the rules. He took the liberty of then expressing his views to them and the committee that where rules were multiplied they were multiplying their weaknesses. There were certain points which were strong common to both. Every set of rules had weak points; and the more rules they had, therefore the more weak points. The result really came to this, that if they were to begin to set up an installation they had it wired, and practically any contractor who was not of high moral tone would take advantage of those things and take all the weak points together, and be strictly within the letter of the law, but still have an installation really in a non-satisfactory state. Now, what Mr. Heaphy said with regard to the Phœnix Office was very true, Some considerable time ago, he believed

Digitized by Google

in May, in 1882, the rules known as the Phœnix Rules were first published in *The Times* newspaper. Since that time the Phœnix Office had devoted its attention very largely to the subject of electric lighting, one which was vital to them. All other offices at that time were almost unanimous in saying electricity was an unknown factor; one with which they might burn their fingers, and one with which they would have nothing to do. To the Phœnix Office they owed a debt of gratitude (cheers) for having set up these rules; and not content merely with having set up rules for every advance in the science that they all had at heart, but for every new discovery the Phœnix had fairly gone into the question, and investigated it, and seen how it could be dealt with in the fire risk, and modified their rules so as to bring these new inventions into fair play. Well, they had found out that at the Grosvenor Gallery the installations which had been set up in accordance with the Phœnix Rules, and which had been passed by an inspector of the Phœnix Office, were the most satisfactory of any that could be done or that they had come across. They had certainly as large an experience as anybody in this kingdom. They had at the present time a considerable number of lights running; they had an output of over 20,000 lights daily. They were putting on installations at the rate of something like ten houses a day. They found in certain cases (he would not give any particulars, but allow them to guess what he meant to allude to) that the work was not done to the satisfaction of the fire office. The result of that was that under certain rules work might be passed by inspectors to their satisfaction; but it was absolutely and entirely prejudicial to their interests as producers of electricity and as distributors of current, because the work in their opinion was absolutely unsafe, and he might inform them now that having this in view they had come to the determination at the Grosvenor Gallery that in future any installation that came to them which had not been wired under the Phœnix Rules, which had not been inspected for the Phœnix Office, would have to be inspected again under the Phœnix Rules before they turned a current into the house (applause). In making this statement he was aware that it was a strong statement to make, but they had a very great stake in this business. He did not say necessarily that defective work was the fault of the contractor, but he did say in his own case that it was the fault of the person who employed him to put that work in. A man could not make a racehorse out of a donkey, and a man also could not get the best article unless he was willing to pay a proper price for it, and that was the fair English of it (applause). He thought the sooner the bogus installations were stamped out in this trade the sooner they should have the electric light taking its place as a recognised commercial business in London (applause). There was only one other thing that he might be allowed to mention; he thought Mr. Crompton might have made a little mistake when he spoke of their using at the Grosvenor Gallery 18lbs. of coal per horse-power, and he stated he could prove it. He was afraid he had misplaced a decimal point—if he said 1·8 he would have been right (laughter).

Mr. WHARTON (of the firm of Laing, Wharton and Down) said the question of these rules was of very great importance to two classes of persons, one the electric light contractors and the other the insurance offices. The question was, did they require any alteration in the standard up to the present? He was taking the Phœnix Rules as the standard. The contractors, he took it—those who did honest work—did not require any alteration. Fires had not occurred under the rules, and although Mr. Heaphy was very strict, he was not too strict. Did the fire insurance companies require any alterations? (cries of "Yes" and "No"). He thought not. Up to the present moment he thought a fire had never occurred where the Phœnix Rules had been faithfully carried out.

Mr. HEAPHY: Not one.

Mr. WHARTON: Those were the classes of persons most interested in a change in the Fire Insurance rules. It appeared to him that neither of them required a change; but if any alteration was to be made, what kind of alteration was that to be? It must be for the worse, it seemed to him. As a matter of sentiment and with respect to the parentage of the rules, Mr. Heaphy had put it to them very happily that night, and they must all acknowledge that he had done very good work, and was entitled to the honour (applause). For himself, as a contractor, he did not want any alteration.

Mr. SHOOLBRED said he thought a good deal of feeling had been imported into the discussion by the non-attention to one particular paragraph, the second one at the commencement of the Society's Rules, which said that it is to be understood that those general rules were not intended to supersede any detailed rules which fire offices might issue for their own protection. He understood it was meant by the committee generally—and he had attended many of the meetings—that there was no intention whatever to create, as it were, antagonism between those rules and those of the Phœnix or any other fire offices. The re-appointment of the committee was, he understood, at the request of several of the fire offices, in order to lay down certain scientific principles——

Mr. HEAPHY: Certainly.

Mr. SHOOLBRED: Scientific principles upon which fire offices might themselves, quite independently of these rules, formulate others for their own guidance, taking these rules or not into consideration. These rules were to a certain extent based upon abstract principles. The fire office rules had to deal with various risks, and other matters of application, which these rules did not pretend to do.

Mr. PRYOR, Chairman of the Fire Office Committee, said he should prefer not to speak in any way on the part of the offices generally, as he might perhaps, but only on behalf of his own office (the Sun) to say that he could not admit Mr. Heaphy's position, or understand why he should feel surprised that the other offices did not accept the statement that the rules were accepted by the leading fire offices, because they were not so accepted, and the statement was absolutely false (hear, hear). They were accepted by some offices certainly—not in any sense by the leading offices, although by some important offices. Therefore there was some little feeling aroused by so direct a misstatement. With regard to the rules, and the reasons so many offices did not accept them, the reason was this: The fire offices were not in a position to protect the contractors for the supply of electric lighting. They quite admitted that on the whole good installations were safe installations, and therefore satisfactory to them, but they had no concern with any possible waste at the expense of the contractors, and they did not intend, he was sure, to protect the contractors in any way. They wished to protect themselves against undue fire risks, and by so doing they would prevent increasing the cost to the public where electric lighting installations were established. They were therefore very anxious, of course, to lay down rules; but he was sure that most of them were not anxious to make it necessary that inspectors should be employed in all cases. It appeared to them to be no more their business to inspect installations than to inspect gas lighting installations. They had nothing to do with anything but to estimate the risk produced by any given cause, and there they intended to draw the line. In the present tentative state of the question inspection was necessary, and they made it, but they could not look upon it as a permanent state of things. They therefore could not accept rules which were drawn so as to involve the necessity of satisfying certain inspectors. They were not, from their point of view, working rules. They wished to use rules laid down which would cover principles and be fairly easily applied, and, where tests were necessary, that those tests should be easily made. Beyond that they did not wish to go. It was perfectly clear that if electric lighting took the place which he trusted and hoped it would take, inspection of every installation in every house would be perfectly and absolutely impossible; it would be a great annoyance to the householder and no benefit whatever to the insurance offices. Therefore the Phœnix Rules were, from his point of view, inadmissible wholly, when electric lighting became as prevalent, as he supposed it would, as gas lighting.

Mr. HEAPHY: May I ask whether Mr. Pryor is speaking for his own office (the Sun) or for other offices?

The CHAIRMAN ruled that Mr. Heaphy was out of order.

Mr. RAWLINS said: Mr. President and Gentlemen, as a member of the Society and surveyor of the Kent Insurance Company I have to claim your indulgence for a few moments. I regret that I was not present on the last occasion in order that I might have heard the complimentary remarks made by Mr. Preece upon the rules as to electric lighting issued by the Guardian, the Kent, and other insurance companies. I think those remarks are to be regretted; but probably Mr. Preece meant them to be interpreted in a "Pickwickian" sense. I daresay it has struck you, gentlemen, as being singular that two members of the Council who spoke on the last occasion should after their arduous labours, extending over nearly twelve months, have been anxious to throw over the new rules of this Society, which they had assisted in framing, for those of the Phœnix, which are not, I should consider, favourable to electricians generally, as they seem to point to the necessity of the surveyor of the fire office superintending the installation on behalf of the insurer, and then on behalf of the fire office passing judgment on himself. One illustration I should like to give of the Phœnix Rules. "All conductors to have sufficient sectional area, so as to allow at least 100 per cent. more electricity being safely sent through them than will ever possibly be required for the lights they supply. Under certain circumstances the inspector may give permission for a larger quantity of current to be sent through a given section of conductor than the proportion above named, and under certain circumstances he may require a lower quantity to be used. Problem.—It is required to find the necessary area of the conductor." The advantages that are claimed for our rules are that they are not copyright; that no charge is made for them; that any insurance company may adopt them, or any part of them; and they do not require the services either of a honorary or a paid interpreter. These rules were drafted in the latter part of last year, the reason being that it seemed doubtful whether the new rules of the Society would ever see the light; and the rules of the Society of 1882 and 1883, under which we had previously worked, were in abeyance. We do not claim in any way to usurp the functions of electricians in regard to electric light installations; but hope that our requirements being, as we consider, so clearly set forth, contractors will be able to carry out their work without the slightest friction between us.

Mr. HAMMOND thought it would be well to suggest to Mr. Preece that in his reply he might take advantage of all the leading companies being represented there that evening to impress upon them the great desirability of not only admitting the electric lighted premises at the same rate as the gas lighted premises, but at a considerable reduction (applause).

Mr. PREECE, in reply, said the discussion on this Paper had taken a very different course to that which he contemplated, viz., to bring the matter before the Society on the question of fire insurance risks incidental to electric lighting. His hope was that by bringing before them several examples of serious cases of accident that they might have elicited from members of the Society other cases and accidents that, to the majority of them, were novel and interesting. Unfortunately, owing to the necessity of his having to refer to the action of the committee and to the rules that were brought out, matters quite foreign to the risks incidental to electric lighting had been imported into this discussion. He did not propose to refer in any shape or form to the burning question to some of them—he simply wished to refer to one or two points that were more of a scientific interest than a personal one. There was only one thing he should like first of all to point out: some speakers seemed to think that the risks connected with electric lighting and the rules drawn up to reduce those risks to a minimum were questions that simply affected insurance offices and contractors. He protested against that with all his power (hear, hear), and he said that the

Digitized by Google

people here most interested were the users of the electric light (applause). He himself said that the chief object of the rules, and the chief reason why the Society of Telegraph-Engineers took up the subject at all, was to protect the users of the electric light from what he called the rapacity of certain contractors. Again the discussion had, to his mind, proved the truth of a very old proverb, and the discussion which was ended by Mr. Crompton was also a proof of the same proverb, which was this, "That a man convinced against his will is of the same opinion still" (laughter). He did not know that really either the result of the great contest that they had had on the question of alternating current and battery distribution as well as the discussion on fire risks had changed the opinion of a single man present (laughter). It had afforded them a great deal of amusement, and they had passed three or four evenings that session he thought far more pleasantly than they would have passed than if they had visited either a theatre or a music hall (laughter.) He was not quite sure that they had added very much to their information or to those scientific facts that this Society was originally constituted to distribute to its members. There was just one point—he did not like to say one word after what he had said—he scarcely liked to refer to his friend Mr. Heaphy, but he did think it was only right to say that this green cover [referring to a pamphlet criticised by Mr. Heaphy] that had been flourished before them was not printed by the Society of Telegraph-Engineers; it was printed and produced in that form by the Phœnix Fire Office.

Mr. HEAPHY: At the desire of the Telegraph-Engineers.

Mr. PREECE: He merely mentioned that because he did not want to say one word of complaint, but he could repeat every word that he had said the other night in praise of what Mr. Heaphy had done towards the improvement of the electric lighting industry (hear, hear). He did not want to raise any further discussion, but he did want to say this, that if he, as chairman of the committee, or as one who took a great personal interest in the question of the distribution of electric light, could in any shape or form further the interests of their science by bringing together the fire offices and the telegraph engineers, or by doing any mortal thing, he was always ready to do it (hear, hear). He wished further to mention one point of a little scientific interest:—Mr. Human, referring to that rule by which one could distinguish or measure the leakage on a system by taking one-5,000th part, wanted to know how they could detect the one-5,000th part of 15 amperes. Well, he did not suppose there was a single telegraphist in this country—he did not think there was a budding electrician in that room who could not, with the simplest galvanometer in his possession, measure at once three milliamperes, and three milliamperes was the one-5,000th part of 15 amperes; so that really the system of measuring a leakage by taking the figures they had named was a matter of very great simplicity. Mr. Shoolbred asked another interesting question, and that was with reference to the question of heating wires. This relation between heat and currents was one that had occupied him more than any other question for the last five or six years. Scarcely a year had passed that he had not brought in some shape or other a Paper before the Royal Society, or before their Society, or before the British Association, developing the relation between the heating effect of currents on currents; and the last Paper which he read was not very long ago, where he gave the constants that would enable them to determine with great accuracy the current that would fuse a wire of any size or any material, and he had been endeavouring within the last few weeks to apply this same formula and these same constants to the case of wires heated to a given temperature above the normal temperature of the atmosphere. Prof. George Forbes, some four or five years ago, gave them a table in which the currents required to raise wires to 9 degrees and to 26 degrees above the normal temperature were calculated; and Mr. Robert Sabine not very long before his death did something of the same kind. But both of these gentlemen based their calculations upon the constant of missivity determined by Mr. Macfarlane in Sir William Thomson's laboratory in Glasgow—that was, the rate of loss of heat per unit area on the surface of a copper sphere when polished and blackened. Now, there was every reason to believe that this constant of Macfarlane's was not applicable to cylinders. Mr. Box wrote a book in the year 1868 where several tables were produced showing the influence of heat in contact with air, and he showed that the law determining the emissivity of spheres and cylinders was different. He (the speaker) was convinced from experiments he had made that they were a little bit in the dark on this question, and he hoped before this session was over that he should be able to put the results of those experiments in such a form that anybody might calculate with exactitude what temperature the wire would acquire with any given current (applause) They could get at it roughly and approximately now, but he was afraid that they were 30 or 40 per cent. out. He did not know that there were any other questions that he had to answer. He could only, in concluding, express a certain amount of regret on his part that his original notion had not been carried out; but it had this advantage, that while there was no question that was of more interest or of more consequence to them than the risks attending electric lighting that question remained to be solved, and therefore there would be reasons why on some future occasion somebody more competent than himself would be able to bring the question before the Society, and let it have a full and free discussion (loud applause).

On the motion of the CHAIRMAN, a vote of thanks was proposed to Mr. Preece for his Paper, and carried by acclamation.

Mr. CROMPTON said he should like to add that it would only be justice to Prof. Forbes, after what he had said that evening, to say that there was a point in which they were completely in accord. Prof. Forbes had reminded him of what was perfectly true, that he (Prof. Forbes) had started the very important subject mentioned in the Paper, namely, the great advantage from underground mains at the same time as he (the speaker) did. If he had himself got the credit of the introduction, it was as much due to Prof. Forbes as himself.

The proceedings then closed.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 12th*, 1888.

We are once more launched on a sea of telephonic controversy. The papers for the re-hearing of the Bell Telephone case have been filed this week in the Supreme Court by the counsel for the People's Telephone Company, which claims, as you are aware, that Daniel Drawbaugh, the village blacksmith of Eberly's Mills, is the real inventor of the telephone. It will be remembered that a distinguished minority of the Supreme Court entered an opinion in Drawbaugh's favour, and encouraged by this, as well as the recent changes in the *personnel* of the Court, this appeal is made: first, on the ground that the Court, in rendering in favour of Bell, erred inadvertently in respect of certain points of facts and of law that were material; and, second, that in consequence of these errors the decision of the Court was against the weight of the evidence. It is not known just what will be done with this appeal. Bell Telephone stock has fallen off a little, standing now about 225. There is some wonder expressed as to where all the money comes from to enable the Drawbaugh people to carry on this fight, especially when it looks so hopeless, and I am informed that a circular has been put out by the president of the People's Company stating that to raise the necessary funds the directors have decided to offer to stockholders 2,000 shares of stock of $100 par value at $6 per share.

It is hard to tell in these days, in America, just where the popular interest in electricity ends. I have recently had occasion to make mention in this letter of several articles in various well-known periodicals, by prominent writers, on electrical topics. But this is only one side of the desire to meet the general curiosity with regard to everything pertaining to electrical applications. Many of the newspapers from week to week devote no small portion of their space to electrical topics. One of the leading papers in St. Louis, for example, serves up to its readers every week an electrical miscellany; while the Omaha *Bee* every Sunday morning lays before the public of that western city three or four columns of the latest electrical items, not merely news, but discussion of scientific questions and topics. All this has its educational side, and must be regarded as full of encouragement. A peculiar evidence of this widespread interest in things electrical was given this week by the *New York World*, which commissioned its celebrated funny man, Bill Nye, to write a comic article on electricity. As you are probably aware the funny man is one of the brightest ornaments of American journalism, and no first-class paper is considered complete unless it has one such humorist on its staff. Bill Nye's reputation is national, and when, therefore, with the aid of illustrations, he expounds his views as to the development of our science for the benefit of a daily paper with a circulation of 250,000 copies, the occasion is one to be noted. I need not ask your readers to follow me into Mr. Nye's description of the manner in which B. Franklin "tapped the low-browed and bellowing nimbus with his buoyant kite," nor into his description of the manner in which the teleseme system keeps its "eye peeled for policemen, and informs the central station where the patrolman is all the time; also as to his temperature, pulse, perspiration, and breath," as you will probably see the article reprinted in England. All will agree with Mr. Nye in the opinion that "electricity and spiritualism have arrived at that stage of perfection where a coil of copper wire and a can of credulity will accomplish a great deal."

The subject of employing wind power for the generation of electric current continues to occupy attention. Not long since I called attention to the figures that had been compiled by Mr. Wolff as to the average rate and duration of breezes in this country, his conclusions being that a good deal of wind power was actually available. The idea is now being given a test by Mr. C. F. Brush at Cleveland, and it is also to have another trial in a large building just being put up at Minneapolis. On the top of this building in a tower will be placed

Digitized by Google

a windmill capable of developing 10 horse-power in a breeze blowing at the rate of 15 miles an hour. This windmill will be geared up to a dynamo, and the dynamo will charge accumulators into which current will pass of course, as soon as the necessary rate of speed isattained. The plant will be arranged with the requisite gauges and meters, and there seems no reason why it should fail. If it succeeds, there will be a good many other plants of the same kind started.

On every hand one continues to hear and see evidences of the great development that is now being experienced in the electric power business. Motors are being put in everywhere, and every one of the motor companies is increasing its capacity for production. Some notion of the extent which the business is assuming may be formed from the fact that the Daft Company have just secured a factory building near this city which has a frontage of 256 feet, 3 stories high, in iron and glass, is supplemented by a brick wing of the same height, 142 by 80 feet, and has a total available floor space of about 85,000 square feet. There are about 2 acres of yard room in which cars can be run. To keep such an establishment as this in full blast requires a plenitude of orders; yet the management of the company have no doubt on this score, but are pushing ahead with the utmost activity, and are the more anxious to be ready because the contracts already on hand are far beyond their present power of execution.

By degrees the necessity of regulating more closely interior installation and street line construction is being recognised, and efforts in various quarters are being made to meet the wants of the case. The Board of Aldermen of this city have just adopted an ordinance requiring that all men handling wires shall carry a numbered badge, so that some check may be put upon indiscriminate handling of the wires, and also on carelessness in putting them up or leaving them loose. At a meeting also of the executive committee of the National Electric Light Association in this city this week steps were taken to look into the subject of licensing the men who are entrusted with wiring and with plants. This work has already been begun by the Boston Electric Exchange, and there is said to be no good reason why the National Electric Association should not take it up, and secure common action throughout the country in this respect. Action is expected when the Association meets here next August.

A testing apparatus for telephone transmitters and induction coils has recently been brought out by Mr. Hammond B. Hayes, of Cambridge, Mass., which may interest some of your telephonic readers. Recognising the difficulty of obtaining the relative value of transmitters and induction coils by the measurement of their effects in absolute units, Mr. Hayes has fallen back on a comparative method, and forthis purpose has devised an arrangement of the induction balance. Thus, he places in connection with a fixed coil the transmitter and induction coil to be tested, and by means of a telephone connected with another movable coil he determines the distance at which the effects in the two are *nil* with different forms of transmitters and coils. It is evident that the relative efficiencies of the different apparatus are in the ratio of the square of the distance between the two coils. In order to obtain a true comparison of the value of the transmitters alone it is, of course, necessary to use the same induction coil, and a constant battery for all experiments; and, *vice versâ*, if it be desired to ascertain the respective merits of a number of induction coils, it would be necessary to employ the same transmitter in all experiments. Another method to which the instrument is applied by Mr. Hayes is the ascertaining of the fall in current along the line. Thus, he first determines the distance between the coils at which silence is obtained when the apparatus is connected in circuit only a few feet from the transmitter. He then observes how much nearer together the coils have to be placed at successively increased distances from the transmitter end of the line. In this manner there can be mapped out with considerable accuracy the conditions of a telephone line, as well as the carrying power of any given transmitter.

A short time ago your Institution of Civil Engineers had a Paper read before it by Dr. Hopkinson "On the Bessbrook and Newry Electric Railroad," and in the discussion which took place on that Paper Mr. W. Lineff cited some figures to show that electrical accumulators laboured under a great disadvantage when compared with the direct system of distribution. These proceedings were published in the electrical papers on this side of the water, and have drawn out a reply from Mr. R. M. Hunter, who is identified with a well-known company here engaged in the exploiting of storage battery street cars, but who also equip on the direct system. Mr. Hunter cites Mr. Lineff, and points out that the latter confessedly left out of the calculation all expenses relating to permanent way, generating plant, &c., and consequently the showing made by the storage battery was far smaller than it would have been if these items had been taken into account in the calculation. Mr. Hunter takes Mr. Lineff's own figures, but includes these items, and arrives at these results: That for a few cars on a long line the electrical accumulator system is the most economical as to cost of equipment, but where a large number of cars are used the central station supply or direct system is the cheapest; the latter can only be put in in large cities by means of expensive conduits, which make it nearer equal to the cost of the accumulator system, and on large roads in densely populated districts where many cars are running. Thus, his tables show that if we ignore the difference in depreciation, to operate 10 cars on four miles of track is cheaper with the accumulator than with line conductors; but owing to the greater depreciation in the accumulator system (accumulators as now made) the line conductor becomes cheapest when we get above eight cars on a four-mile track. Mr. Hunter also avers that there are other points besides cheapness of construction which should be considered in this case, and that the storage battery is well able to compete with direct distribution in many cases.

Lieut. H. Hutchins, of the U. S. Navy, has just published in the *Colliery Engineer* some important experiments on the behaviour of incandescent lamps in explosive gases, and has pointed to the fact that precautions must be taken in the use of these lamps when surrounded by such gases. His experiments—which were made with different lamps—as a rule, consisted in placing the lamp in a box with a glass window, and having an opening inside to admit a steel rod for piercing the bulb. His first experiment with a Swan sixteen candle-power lamp consisted in raising the lamp to a white incandescence, the case being filled with hydrogen and oxygen. When the bulb was pierced the gas exploded immediately, completely shattering the lamp bulb. The carbon filament remained intact, probably due to the fact that the glass bulb was shattered into innumerable fine fragments. The conclusion he reached from these experiments was that the inrush of gas does not break the Swan filament before the gas can become ignited. Consequently in a highly explosive gas the breaking of an incandescent lamp would be dangerous, at least with a filament not less delicate than that of the Swan lamp. In another experiment with marsh gas the gas did explode, but the filament was found to be broken, due to the flying pieces of glass. Next, the Maxim lamp, ruptured in pure coal gas, merely resulted in the deposition of the carbon of the gas upon the filament, or, in other words, in the "flashing" usual in the manufacture of lamps. With coal gas and air mixed another Maxim lamp did not have its filament broken by the inrush of gas, nor by the flying pieces of glass. The lamp continued to burn for a few seconds, then the required temperature being apparently reached the gas exploded, the containing case was lifted 5ft. or 6ft. in the air, and the filament broken by the force of the explosion. From these experiments Lieutenant Hutchins concludes that the incandescent filament, providing it is as tough as either the Swan or Maxim filaments, coming in contact with either a high explosive gas, such as the mixture of hydrogen and oxygen, or a comparatively weak one, such as coal gas and air in explosive proportions, will explode them. And he concludes, finally, that when explosive gases are allowed to collect on board ship from bad ventilation or other causes, incandescent lights, such as are used in these experiments, are dangerous for ship lighting. The moral or lesson as to the necessary precautions is obvious.

"THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your issue of last week on the above subject gives what at the present time must be to many very interesting information in regard to telephone matters, and outsiders will welcome what is given with reference to the Telephone Exchanges in London, as hitherto so little has been brought out with reference to them.

There are some points in the statistics which seem to require explanation, however. I notice in the weekly average of the number of calls the United Company is shown as 221,764, and the National Company as 420,000—which is nearly double for the National; while in the statistics for June, 1887, it is shown that the calls per day are greater for the United than for the National Company—the former having 74,462, while the latter has only 70,000. Can this be right?

I would likewise point out that there is a difficulty in seeing how the United Company, with 4,622 exchange subscribers and 1,003 private, can use as many as 13,477 instruments. Each exchange subscriber requires only one instrument (except in the case of extension lines), while each private line requires, of course, two instruments. The same is to be remarked with reference to all the companies with the exception of the South of England Company, and it seems strange how they can work 1,203 exchange lines and 370 private wires with only 1,667 instruments.

The plan showing the wires connecting the exchanges in London is interesting in so far as it shows how the work is done; but few, I fear, outside of London can approve of this way of doing what is a very important part of telephone exchange work, and in scarcely any of the provincial centres is it done in this manner, the approved way being to establish what is known as a trunk exchange for giving connections between all the different exchanges, a system which is proved to have many decided advantages. This means that a central point is established, and all trunk or junction wires run to that point, the operators at which are provided with what is known as a call wire to as many outside exchanges as they can reply to and operate for. With this call-wire system the operators in the branch exchanges are practically as much in communication with the Central Trunk operators as if sitting by their sides, as no ringing or calling of attention in any way is necessary.

The advantages are obvious, inasmuch that more work can be had out of the wires, and in consequence a fewer number will suffice when run to one point, where they are all under the control of one or more operators, than if divided into a certain number run to several exchanges.—Yours, &c.,

TELEPHONIST.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is perfectly true, as stated by "Telephonist," that very little authentic information has hitherto been available with regard to the work of the metropolitan telephone exchanges. We understand that this has been due in the main to the exigencies of the commercial development of the telephonic work of the country, carried out as it has been by a series of companies working with common interests, but in friendly rivalry. An immense amount of work is continually in progress in connection with the telephone exchange system in London which does not come directly under the public notice, but bears fruit in the ever-increasing efficiency and extension of the telephone service.

The writer is informed, however, that the parent company considers that the time is now ripe for taking the public more fully into their confidence, and that they intend from time to time to make public any particulars which would appear to be of general interest.

The writer has to express his obligations to "Telephonist" for having detected two errors in the figures given. These errors occurred in the figures supplied by the companies, and were not noticed in time to prevent their insertion. The manner in which they occurred is fairly obvious. It may be pointed out, in the first place, that every telephone call involves two messages, the call and the reply, so that the total number of messages is obtained by doubling the number of calls. The number 420,000 given as the total number of "calls" per week in 1887 is really the number of messages, the number of calls being only 210,000. The numbers for the other companies all refer to the calls only, so that the number 210,000 must be subtracted from the final total. With regard to the number of instruments employed, two instruments are required for each exchange wire, namely, a transmitter and a receiver, and more in the case of extension wires, some large firms having as many as 60 or 70 instruments on their premises. In the case of private wires four instruments are required, two at each end; but a small deduction usually has to be made from the total owing to some subscribers possessing both an exchange connection and a private wire, and using the same set of instruments for both; but, on the other hand, the instruments in use in the switch rooms have to be added. In the case of the South of England Company the number 1,667 is clearly too small, and evidently refers to sets of instruments instead of to single instruments.

"Telephonist's" criticism of the London system is entirely beside the mark. A more careful inspection of the diagram and reference to the text would have shown him that the central exchange at Oxford-court is a central trunk exchange, the trunk lines leading to it being shown by the dotted lines in the diagram, as explained in the text. There are, indeed, no subscribers connected directly with the Central Exchange, which is exclusively for trunk lines.

In addition to this, all the exchanges between which there is frequent communication are directly connected by one or more local trunk lines, which greatly facilitates the work; and, besides, it would be the height of imprudence to risk having all the trunk wires in one building, and consequently all subject to derangement by fire or other accident.

The ideally perfect system would be to have every subscriber connected directly to a single central exchange; but this, even if the necessary way-leaves could be obtained, would necessitate the use of wires nine or ten miles in length to connect single subscribers to the exchange.

Failing this, the best system ideally would be to have every exchange directly connected with every other; but this, again, would be physically impossible in London, and the system adopted is a combination of this with the central trunk exchange system which "Telephonist" advocates, while he has failed to perceive that it is actually in use, and is clearly set forth in the diagram which he refers to.

At the present time there are upwards of 300 of these trunk wires working from Oxford-court, and almost as many more local trunks working between the exchanges.—Yours, &c.

THE WRITER OF THE ARTICLES
ON "THE RISE AND PROGRESS OF TELEPHONY
IN THE UNITED KINGDOM."

SYNCHRONOUS MULTIPLEX TELEGRAPHY.

(Translated from the Danish.)

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the issue of your esteemed journal dated the 27th of April last, Mr. Patrick B. Delany has contributed a Paper as a reply to some articles which appeared in the *Electrical Review* during the autumn of 1887, and in which I proved that the synchronism which Mr. Delany applies to his synchronous multiplex telegraphy is essentially mine.

Synchronous multiplex telegraphy comprises three things:—

1. To provide an isochronous motor; *i.e.*, a motor of as even a motion as possible.

Digitized by Google

2. To make two or more isochronous motors at different places to move absolutely synchronously.

3. To connect telegraphic instruments to the motor in such a manner that two and two successively are joined to each other by means of the synchronous motors.

It is well known that synchronous multiplex telegraphy on these principles is not new, that all the methods which formerly were used utilised a less successful isochronous motor —for example, a conical pendulum. Nevertheless, synchronous multiplex telegraphy was largely used, and there were many solutions regarding it; whereas the basis, the isochronous motor, as a rule, was little modified, although greater exactness and simplicity were vastly needed.

My first work in this field was therefore to provide a new foundation, which I did by means of my invention "the phonic wheel." The instrument is based upon a new principle, quite independent of the isochronous motors formerly employed; nay, it even represents a new physical principle, *dynamic stable equilibrium*. It has been described in detail so often that it is quite unnecessary for me to say more about it here; suffice it that it is an invention, which in its relation to a vibrating body—for instance, the tuning fork—is the same as that of a clock to a pendulum.

This invention no one has hitherto disputed as mine. Now, however, Mr. Delany comforts himself that Lord Rayleigh says that he nearly simultaneously with me had the same idea, that he carried out and made it public. I do not consider this circumstance has anything to do with Delany's; it is not the first time that two physicists simultaneously, and yet independently of each other, have had one and the same idea, nor does this detract from the honour of either. On the contrary, it is not to Mr. Delany's credit when he says that Lord Rayleigh's instrument was "exhibited with a detailed statement of the theory of its operation at a meeting of the Physical Society on the 30th of March, 1878, and published in *Nature*, May 23rd, 1878," while he suppresses—what cannot have escaped his observation in my reply to Lord Rayleigh—that "on the 22nd of February, 1878, Prof. Holten laid my invention before the Royal Danish Academy of Sciences, and on the 8th of March, 1878, my pamphlet, 'Tonehjulet' ('La Roue Phonique') was published in Copenhagen." The reason that Lord Rayleigh has not raised any remonstrance against Delany's synchronism is probably simply this, that Lord Rayleigh never intended nor tried to use his instrument in this direction, but only mentions that "an application to the determination of absolute pitch is given as an appendix to one of my Papers upon the ohm (*Phil. Trans.*, 1883, page 295). It has sometimes appeared to me that the principle might be applied to regulation of equatorial telescopes;" while my pamphlet of the 8th of March, 1878, points out a variety of applications, and especially the enormous importance of the phonic wheel for synchronism. It is, therefore, and because I have introduced the principle of the synchronism which Mr. Delany uses, that I have strong reasons for objection, and I say, as before—and history will doubtless confirm my view—that the phonic wheel is the very base and foundation of the new synchronous multiplex telegraphy. The scientific principle of this instrument will maintain its ground long after Mr. Delany's special application of it is forgotten, and it will be no slight to me, but an honour, when, then, Lord Rayleigh's name will be named together with mine.

When, on the other hand, a powerful company as the "Standard Electric Manufacturing Company," of New York, with Mr. Fred. P. Jones as President and Mr. Patrick B. Delany as electrician, thinks it becoming to wage an economic war against a poor scientist instead of coming to terms with him, then this proceeding is not either unknown in the history of science and its applications. In the United States I have been paid what I asked; but in Europe, where I could not afford to renew my original patents for the phonic wheel, and where the matter could be completely secured by patents for the synchronism, even when I sold my American patent, they have been simply appropriated. With the money I received I was enabled to patent the improved synchronism in Europe, shortly after having sent Mr. Jones a description of it, while Mr. Delany just a year after patented the same synchronism with some modification in the description. After this the synchronism belonged to me in Europe, not only morally but legally. Now Mr. Delany says that he has about 20 patents. Everybody who knows anything at all about waging war with patents knows also that it requires a long purse, especially, as in this case, when it is Mr. Delany who is to be attacked, for instance in England, while his patents belong to a company in America. As far as pecuniary support is concerned I am not a match for Delany.

It will be observed that there is here a question of two different synchronisms. *The first* rests upon the law that when a tuning fork is acted upon by attraction or repulsion, corresponding approximately with its own pitch, it will oscillate perfectly in accordance with these and not with its own pitch. This was thus utilised: Impulses from station 1 kept a tuning fork at station 2 in absolute synchronous movement. *The second* synchronism aims at sending a correction current from station 1 for each revolution by which an independent oscillating tuning fork at station 2 is kept in automatic synchronism with that at station 1.

The Americans have now proceeded as follows: First and foremost they have endeavoured to preserve for me the honour of the first synchronism, in the hope that attention should thereby be drawn from the fact that the second likewise is mine; they further sought to maintain that the first is an impossibility. I have already spent too much time in proving that the first synchronism was good. I have another and later one, patented in 1881, which is better. It is misleading to continue to negotiate about the first; Mr. Delany, however, still treats of the first one. He insinuates continually that there never was real synchronism, but only something that was kept going by means of a "turntable," and to prove it Mr. Delany speaks of the small amount of work that was done on the line. He overlooks what I have so often said, viz., that I do not pretend ever to have invented a telegraphic system; and after having solved the first part of the problem, viz., the isochronous motor, I went to work on the second part, the synchronism. It was this I accomplished and tried in 1880 between Frederica and Nyborg. It is impossible to make Mr. Delany understand that synchronism is one thing and telegraphy another. If I try the synchronism with galvanometers, I do not pretend to have made a galvanometric invention, nor a telegraphic one because I employ telegraph instruments.

Mr. Delany, however, gives a means of settling the dispute. He says (*Electrician*, April 27, page 715): "If Mr. la Cour will pardon the suggestion, I would advise him to repeat his Frederica and Nyborg demonstration, unless synchronism on that plan has become a lost art. Its reproduction would throw much light on this question. If he succeed without the turntable, then I will publicly recant all my doubtings."

Well, I take him at his word on two conditions. First, that by "all my doubtings" is understood not only the possibility of this synchronism but also my improved synchronism, patented in 1882, which he, by-the-bye, does not appear to doubt so much; and, secondly, when he not only will recant publicly "all his doubtings," but also, without it being necessary for me to go to law with him about his European patents, will pay me for the encroachment, which he by these has made upon my rights, the sum of £10,000 sterling. As a matter of course I cannot spend time and money on a demonstration without gaining something by it; and to all impartial men I am in possession of a sufficiently distinct declaration by the Danish officials (see *Electrical Review*, September 30th, 1887) without going to further trouble. If Delany is so sure that neither the first nor the second synchronism is workable, he can safely accept my offer. I require naturally a guarantee that Mr. Delany will fulfil his part of the arrangement, and it would be better if Mr. Delany himself, or some competent person, be present, and certify that the synchronism really keeps in order from morning until night *automatically*, and *without the use of a turntable*.

After this offer on my part it is not necessary to consider further the "improved synchronism," which by-the-bye is the

Digitized by Google

main point, as it is this Mr. Delany has appropriated. The reason why I have not been fortunate enough to make use of the system practically is easily understood from the fact that I never took the final step in synchronous multiplex telegraphy, *i.e.*, to construct telegraph instruments; and Governments and telegraph companies are not disposed to introduce anything but complete telegraphic systems. *The perfection and simplicity of my synchronism have in all cases* been acknowledged and demonstrated (see *Electrical Review*, October 7th, 1887), and it is further absolutely unfounded on the part of Mr. Delany to write that the synchronism which M. Cassagnes uses, and which is attested by the French Government, is not mine, but his. It is true that they are difficult to distinguish, but M. Cassagnes has not employed anything whatever except what is indicated in my patent, which is a year older than Delany's. The only thing to be seen on Mr. Cassagnes' drawing that is somewhat different from mine is that he varies the strength of the current in the receiving fork by the insertion of larger or smaller *resistances*, whereas my drawings show the application of a higher or lower *electromotive force*. This is no greater difference in the electrical world than a nail or a screw amongst joiners, and I have been careful enough to remove all misunderstanding, for I claim "*by varying the strength of the current that operates the tuning fork.*"

As Mr. Delany's arrangement of the improved synchronism is so similar to mine that he has not been able to distinguish them in Cassagnes' installation, there is only one excuse for his interference—namely, that he has added that very part which changed my synchronism from impossibility into possibility; and if Mr. Delany accepts my above named offer, I shall further prove to him that an arrangement in all its details corresponding to and identical with the particular parts of my patent—I cannot afford to multiply them into twenty patents—also works with absolute precision from morning till night. I may add that I shall publicly withdraw any claim on Delany's synchronism if both demonstrations do not succeed perfectly.

It is quite superfluous to reply to Mr. Delany's remark that I "make no provision for static discharge." This is a special telegraphic arrangement which I have not been occupied with.

From the certainty with which Mr. Delany, in *The Electrician* of the 27th of April last, speaks of the impossibility of my synchronism, and from the offer I have here made, it will now be seen whether the Americans have acted in good faith when they appropriated rights which in their opinion were worthless, or if the whole is only a manœuvre, similar to those practised on several other occasions, the object of which is to make a large profit without coming to terms with the rightful inventor.—Yours, &c., PAUL LA COUR.

Copenhagen, May 18, 1888.

TAVENER'S COULOMB METER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the current issue of a contemporary journal appears a notice of an electric meter said to be of Prof. Elihu Thomson's design, and a note also appeared in your journal on the 11th inst. describing the same meter and attributing its design to the same gentleman. Now, as these notes are calculated to mislead, I think it is only right to state that the principle upon which this meter works has already been adopted by Tavener in his meter, a notice of which appeared in your journal on December 16th, 1887. The principle involved is that of utilising the heating property of the current for producing an oscillating motion of the containing tube, and consequent registration of the quantity of electricity, whether by continuous or alternating currents, passing through the circuit.

As Prof. Thomson has designed his meter on exactly similar lines as Tavener, and as his, moreover, bears upon it evidence of a knowledge of the prior existence of Tavener's meter, it appears to me that to the last-named is due the credit for the ingenuity manifested in the production of a meter working on a principle differing so completely from those upon which current meters have hitherto been designed and worked.

Honour to whom honour is due; to originate a meter working on the principle I have delineated, which shall register accurately the amount of current passing through it at any time, is one thing, while to copy such a meter and calmly to appropriate its invention is quite another.—Yours &c.,

WILLIAM PHILLIPS MENDHAM.

Western Electrical Works, Bristol, May 22, 1888.

JARMAN'S ELECTRIC TRAM CAR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I observe your notice upon Messrs. F. Walker and Hyde's report *re* the electric tramcar that bears my name. Perhaps this report was not so full as might be desired; this, however, will before long be forthcoming. The trials recently made with this car prove, as near as proof can be got outside everyday working, that tramcar propulsion by stored electric energy will, ere long, take its place in competition with horses. If the life of the accumulators proves what is expected then there will be no fear of a real commercial success.

Respecting the double armature motor, which has been the subject of some remark, I can only state that I more than ever rigidly adhere to this plan for every trial yet made with this car proves its advantage. No matter the number of stoppages, this plan enables the time to be kept on the outward or homeward journeys, a point so necessary in tramway traffic.

There is every prospect before long of having a couple or more of these cars running upon one of the suburban lines, which will enable the electrical, engineering and commercial values to be fully proved.—Yours, &c., A. J. JARMAN.

Brixton, S.W.. May 23rd, 1888.

PATENT RECORD.

RECENT APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

5,522. A. H. G. SEGNITZ (of the firm of Rösing Brothers and Co.), London. Improvements in telephonic apparatus (E. Brand, Brazil). April 13, 1888.

5,528. E. HERMITE, E. J. PATERSON, and C. F. COOPER. London. An improvement in plates for voltaic batteries. April 13, 1888.

5,529. P. G. MERRY. London. Improved construction of reflector for use with incandescent electric lamps to facilitate its removal or re-adjustment.

5,531. J. G. STATTER. London. A new or improved system of electric lighting and apparatus therefor. April 13, 1888.

5,586. H. H. LAKE. London. Improvements relating to holders or supports for electric incandescent lamps and to contact devices for use therein, and for other purposes (C. Grivolas, France). April 14, 1888.

5,640. H. EDMUNDS. London. Improved means to be used in supplying, distributing, controlling, and indicating electricity for lighting and other purposes. April 16, 1888.

5,681. C. S. SNELL. Saltash. Improvements in switches used for electrical purposes. April 17, 1888.

5,704. J. S. RAWORTH. London. Improvements in switch-boards or apparatus for the distribution of electricity. April 17, 1888.

5,708. J. LEA and C. JULIAN. London. Improvements in dynamo-electric machines and motors. April 17, 1888.

5,713. J. K. HALLOCK and J. C. BLICKENSDERFER. London. Improvements in electric elevators. April 17, 1888.

5,723. W. WEBSTER. London. The production of chalybeate waters by electrolytic action and apparatus therefor. April 17, 1888.

5,731. H. H. LAKE. London. Improvements in and relating to apparatus for measuring electric currents, which apparatus will also serve as a motor (E. Thomson, United States). April 17, 1888.

5,732. H. H. LAKE. London. Improvements in and relating to apparatus for measuring electric currents, which apparatus will also serve as a motor (E. Thomson, United States). April 17, 1888.

5,745. S. H. GILLAM. Bridgwater. An instrument for use in making electrical contacts. April 18, 1888.

5,753. G. HUCK. Burnley. "The Daisy" long-distance telephone and transmitter. April 18, 1888.

5,782. W. C. MOUNTAIN. London. A new or improved electric arc lamp. April 18, 1888.

COMPANIES' MEETINGS.

The Bournemouth Electric Light and Power Company (Limited).

The first general meeting of the shareholders of this Company was held on the 15th inst. at the Fine Art Gallery, Palmerston Lodge, Old Christchurch-road, Bournemouth. Dr. Nunn was voted to the chair, and called upon the secretary to read the Directors' report and the financial statement, which were adopted without a dissentient.

The election of officers for the ensuing year was next proceeded with. The names of those gentlemen who had qualified for the post of Director, or who had the intention of doing so, were—Major-General Hutchinson, Mr. D. M. Fox, Mr. A. H. Sanderson, Mr. W. A. Smith, Mr. J. Donkin, Mr. G. J. Piercy, Capt. Williams, R.N., Dr. Dewes, and Mr. J. S. Helyer. Dr. Dewes declined to stand, and Mr. Helyer, the originator and promoter of the Company, also withdrew, whereupon the names of the first seven gentlemen were put to the vote, and they were afterwards declared elected. Mr. H. T. Trevanion was appointed solicitor to the Company; Messrs. Wheatley and Cridland were appointed auditors in the room of Mr. Atkinson; and Mr. W. E. Shakell was re-elected secretary. Mr. Shepherd was appointed manager of the works.

A vote of thanks to the Chairman concluded the proceedings.

We understand that the work of laying down the plant is nearly completed, and it is expected that lights will be running within a month from the present date.

Schmidt Douglas Electric Company (Limited).

The first annual meeting of the shareholders of this Company was held at the Alexandra Hotel, Bradford, on Thursday, the 17th inst. The chair was occupied by Dr. Bowman, the Chairman of the Company.

The annual report and balance-sheet were adopted. The accounts showed a profit of 7½ per cent. on the year's working, carrying forward £400 to the reserve fund.

The CHAIRMAN stated that in consequence of alterations in the premises the Company had only virtually been working for six months, and had large contracts uncompleted.

It was decided by the shareholders for the present to carry the dividend to a suspense account, so as not to interfere with the working capital of the Company.

The CHAIRMAN of the Company spoke hopefully of the future prospects of electric lighting, and said that if a larger number of shareholders could be obtained there was no doubt but that the business of the Company could be made highly remunerative.

At the conclusion, a vote of thanks to the Chairman and the Directors was moved by Alderman FREDERICK PRIESTMAN and seconded by Mr. STEPHENSON.

NEW COMPANIES REGISTERED.

THE WATERWORKS, GAS AND GENERAL LIGHTING CORPORATION (LIMITED).—Registered by R. B. Johnson 50, Parliament-street, Westminster. Capital £1,000,000, divided into 100,000 shares of £10 each. Object, to promote and assist in promoting waterworks, gasworks, hydraulic works, electric and other lighting works, and the business of supply connected with them, or any of them, in the United Kingdom or India or in any foreign country or in any colony or dependency of the United Kingdom or India. The first subscribers are:—

	Shares.
J. J. Gibson, 22, Noyna-road, Tooting, S.W.	1
H. J. Hogarth, 24, Hanover-gardens, Kennington, S.E.	1
H. J. Newell, estate agent, 7, Railway-terrace, Wemby, N.W.	1
R. Thorp, mantle manufacturer, 44, Farringdon-street	1
A. Bell, accountant, 17, Springdale-road, Stoke Newington, N.	1
A. Martin, accountant, 23, Billifield-road, Brixton, S.W.	1
M. Ross, 3, Queen Anne's-gardens, Bedford-park	1
E. Thomson, clerk, 73, Linnell-road, Camberwell, S.E.	1
W. Whittington, 53, Fleming-road, S.E.	1

The number of directors shall not be more than 11 nor less than three. The first directors shall be appointed by the subscribers to the Memorandum of Association. The qualification of every director shall be the holding of not less than £2,000 in stock or shares of the company. The directors shall be paid the sum of £100 per annum each for their services to the company.

BRITISH ASSOCIATION OF MEDICAL ELECTRICIANS.—This association was registered on the 5th inst., as an unlimited company without specified capital, to promote and encourage the study and practice of medical electricity. The subscribers are:—

C. B. Harness, Potter's Bar, consulting medical electrician.
J. F. Leesen, L.R.C.P., 57, Church-road, Brighton.
H. C. R. Sharman, 1, Maley-terrace, Lower Norwood.
C. B. Hollier, Oakbrew, Streatham, consulting electrician.
J. H. Hodges, 16, Great Ormond-street, medical electrician.
Prof. Carter Moffatt, Northumberland Park, N.
A. Smith, 1, Rathbone-place, W.

The management will be vested in a council.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN

The Right Hon. LORD SUDELEY, P.C., F.R.S.
LEOPOLD SALOMONS, Esq.
JOHN C. SALT, Esq.
C. A. WHITMORE, Esq., M.P.

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 524.—Vol. XXI. FRIDAY, JUNE 1, 1888. Price 4d.

NOTES.

The enthusiasm which greeted the appearance of Sir William Thomson at the Society of Telegraph-Engineers and Electricians is a significant mark of the profound esteem in which his name is universally held as that of the greatest physicist of the age. But the series of brief speeches which followed Sir William's address, and took the place of the customary discussion, coming, as they did, from men in the front rank of the profession, formed a tribute of respect and admiration such as perhaps no other living scientist could command, and to which it would be superfluous to add any words of our own. We shall publish our report of Sir William's address in a subsequent issue, when we hope to fully illustrate it.

We insert in our columns this week an article on electrical traction, written by a German engineer who may be assumed to have had some considerable experince in that subject. We think it desirable, however, to note that the general theory therein stated is not entirely in agreement with the views usually held amongst English electricians. In the first place, there seems to be a certain amount of confusion between the torque of a motor and its brake horse-power. Herr Coerper tells us that a motor should develop its maximum power at starting, and that an electrical motor, as ordinarily constructed, gives out its minimum power when doing so. The problem appears to be misunderstood. What is required at starting is maximum torque and not maximum work, and this is precisely what a motor does give. (For the sake of students we may recall the fact that torque is measured in pound-feet and is independent of time, while the work done is the product of the torque and the time taken to make any number of revolutions of the armature or rolling wheels according to the units chosen.) Considered from this point of view, we are afraid that the ingenious device designed by Herr Coerper to give maximum power at starting is really only a complicated friction clutch. At the same time a device of this character may sometimes prove very useful where stoppages and slow speeds are frequent, as it tends to obviate undue heating of the motor.

In our last issue we printed a letter from Mr. Jarman, whose "system" of electric traction is receiving a trial upon one of the South London tramway lines. It will be remembered that the special feature of Mr. Jarman's scheme consists in the employment of two motors, one to drive the car in each direction. To this plan, says Mr. Jarman, "I more than ever rigidly adhere." Since, then, our criticism is challenged, we feel bound to say that we also adhere with equal rigidity to our first opinion (expressed some two years ago), namely, that the use of two motors where one will serve the purpose is a wasteful and unnecessary complication. Mr. Jarman takes it for granted that the heating of the motor is the chief difficulty to be overcome in electric traction; but no electrical engineer (*pace* Mr. Jarman) requires to be convinced that the remedy first to be tried simply consists in making the motor large enough for the work it has to do. At the same time we recognise the possibility, to which we have alluded above, of even a well-designed motor getting into trouble from this cause where the load is heavy and stoppages or slow speeds are frequent. But even this does not seem to necessitate two motors; it points rather to the use of some such gearing as that adopted by the Helios Company. A somewhat similar solution, proposed some time ago, we believe, by Mr. Radcliffe Ward, is perhaps still better because more positive; it consists in the use of two sets of driving gear of different ratios, the large ratio being used for the start and the smaller ratio when going at full speed. However, if Mr. Jarman will use one motor of proper dimensions and suitable design, we have little doubt that he will find it much cheaper and more satisfactory than the employment of two small motors each of which gets uncomfortably hot.

In this issue we give the concluding part of the short series of Papers on the history of continuous-current transformation which Mr. Percy Sellon has contributed to our columns. That the last word has yet to be spoken on this subject everyone admits; what we now want is to see some experiments in this method of distribution upon a practical scale. We are sorry that nothing of the kind is being done this year, so far as we are aware, at any of the Exhibitions. The Glasgow Exhibition would have formed a favourable field for a trial of the system on a suitable scale. The question of regulation probably offers a rather serious difficulty. Mr. Sellon mentions a patent of Mr. Swinburne's (with the details of which we are unacquainted), in which a method of regulation by some kind of compound winding is spoken of. It is, however, rather difficult to see how this can be done, since both armature windings are moving through the same field and both must be equally affected by whatever affects that field. But it would be rash to pronounce

Digitized by Google

judgment on Mr. SWINBURNE'S device before we know something more about it. For our own part we are still inclined to think the revolving commutator arrangement designed by Mr. F. JEHL, and described in *The Electrician* of October 28th, 1887, page 514, and December 2nd, page 75, as promising a device as any yet described.

A. FOEPPL (in Wiedemann's *Annalen*, Vol. XXXIII., page 492, 1888) describes some experiments he has been making on the conductivity of a vacuum. The results obtained are negative, but the method employed is extremely pretty. Herr FOEPPL uses a coiled glass tube as the secondary of a transformer, the ends being continued to some distance and then joined to the terminals of a galvanometer coil, also made of glass tube. Arrangements are made for exhausting the tube. He thus obtains a circuit consisting *wholly* of rarefied air, and avoids transition resistances. The results, however, as we have already said, are negative, as on making or breaking the primary circuit no deflection was obtainable on the galvanometer. From this Herr FOEPPL shows the resistance of the air cannot be less than 3×10^6 that of copper.

FROM the latest returns we gather that the visible supply of copper is at the present time larger than it has been for many years past. Not only has production been stimulated by the present high price, but the consumption has been seriously diminished by the substitution of mild steel and iron wherever these materials are admissible. In several industries, where copper was formerly used, it will henceforth probably be dispensed with altogether. Large quantities of old copper and brass have also been thrown on the market within the last few weeks, especially by the railway companies. In view of these facts it is anticipated in some quarters that a fall will take place before many months are over. But it would probably be unwise to reckon too confidently upon this.

LORD ONSLOW'S proposed Bill to enable Lloyds to acquire sites and construct telegraph lines for coast-signalling purposes will apparently not be allowed to pass unchallenged. To the merits of the proposal, taken by itself, no objection can reasonably be urged; but, considered as part of our national defences, it is altogether illusory, and is only calculated to postpone indefinitely the scheme for providing the whole of the coast with a continuous line of telegraphs, which is now so much needed for outlook purposes in time of war. The present is an opportune moment for having the whole question gone into by a Parliamentary Committee, as suggested in Mr. BAYLEY'S letter to *The Times*, reprinted by us last week. We have no doubt that Lloyds would be quite willing to abandon their project if the country would take up the larger scheme as a national affair. That it would probably pay for itself in time of peace by its service to the mercantile marine, and in the succour it would lend to ships in distress, is pretty evident from the fact of a private corporation offering to undertake the business.

At the Chicago Electric Club some discussion recently took place on a point which will most likely come under consideration before long in this country. It is agreed that within a certain limited area a simple parallel distribution is the cheapest. Supposing, then, it be decided to light a district by alternating transformers, the question is whether a commencement should be made in the area immediately around the station with direct currents. We have heard several people express an opinion in favour of this plan, and it also appears that it has commended itself to many electricians in America. But from the discussion above alluded to, we gather that practical experience does not recommend it. Mr. CUTTER, of the Thomson Houston Company, spoke very strongly in favour of a single unmixed system for central station work. A mixed system is nearly always more expensive to work, it necessitates additional reserve plant, and is likely to lead to mistakes on the part of the *employés*. We are, moreover, inclined to think that in this country it is especially undesirable to go through the early—and to some extent experimental—stage twice over. The slight additional first cost of transformers in the nearest houses will probably pay for itself by the additional experience gained, to say nothing further of the extra cost of the mixed system to which allusion has already been made.

OUR recent observations upon the state of affairs at Leamington have called forth a reply from Messrs. CHAMBERLAIN AND HOOKHAM which will be found in our correspondence columns. We are quite unable to admit that we have acted either with unseemly haste or without due and full consideration in this matter. Our remarks were based upon the published reports of the proceedings of the Leamington Town Council, abstracts of which appeared in our columns on January 20th, March 9th, April 6th and May 25th. We now learn for the first time that the proceedings of the Town Council were "not to be taken seriously as criticisms on electric lighting, but only as illustrations of personal pique or of trade rivalry." We shall be the first to rejoice if it can be shown that nothing more serious than this is the matter; but, if so, we think it a very great pity that Messrs. CHAMBERLAIN AND HOOKHAM have not long ago taken the trouble to let the facts be known. For months past the gas journals have been rejoicing over the alleged failure of the electric light at Leamington, and it is within our positive knowledge that the reports have done no little mischief to the prospects of electric lighting in other localities. It was an instance of this kind, coupled with the result of the motion brought before the Town Council a fortnight ago, that led us to think that the time had come when it was due to the profession generally that the matter should be cleared up. It is especially noteworthy that, with the single exception of the Mayor, all those speakers who opposed Mr. CROWTHER DAVIES' motion to terminate the agreement did so solely on the ground that they thought the Company should be allowed a further trial. Dr. THURSFIELD, for instance, "thinks the electric light a dismal failure, but still he would not support the motion, as he should like the Company to have a further chance." Mr. SALMON "could not vote for the motion that day, but if the light continued as at present, at some not very distant period such a notice would have to be given." (See *Electrician*, May 25th, p. 73.) Several other speakers followed to the same effect. Messrs. CHAMBERLAIN AND HOOKHAM should evidently pray

Digitized by Google

rather to be saved from their friends than from their trade rivals. We intend shortly to avail ourselves of this invitation to visit Leamington, which we hope may not be countermanded, as was a similar invitation accepted by us some months ago.

WE have so often complained of the daily press in its treatment of electrical subjects that we hasten to pay a high compliment to the *Morning Post*, which on Saturday last published an article on Lord THURLOW'S Electric Lighting Bill quite exceptional both in tone and intelligence. Among other sensible things which are said in that article we note with pleasure a confirmation of our own oft-repeated contention that if Parliament had enforced upon railway projects, canals, docks, gasworks, and waterworks the conditions it now endeavours to apply to electric lighting, we should have had to do without those things altogether, unless Parliament itself had undertaken to provide them.

So long as the State, or the local authorities, are not prepared to take up a new enterprise for fear of the losses, so long must they be content to let private speculation take its chance of the gains. On this point the *Morning Post* expresses itself with more hesitancy than there is any occasion for. We fear it is not likely that new discoveries may lead to the production and delivery of electric light at "a fraction of its present cost;" but even admitting the possibility of such an eventuality, what then? The recognition of future contingencies could operate only in one of two ways—either we must assume that they will be realised, which would meanwhile be extremely unfair, or we must wait until they are realised, which would be extremely foolish. "Gigantic profits," under conditions accepted by Lord THURLOW'S Bill, would be next to impossible. But if the State itself declines to make these profits we see no valid reason why private ventures should not pocket them. From among the innumerable trades and professions in which gigantic profits are made unmolested, it is hard to see why corporations which supply the public with the luxuries of life should be excluded with such venomous hostility.

It will be seen from our report of the proceedings in the incandescent lamp litigation that at the suggestion of Mr. Justice KAY it has been arranged to carry out some experiments upon the manufacture of lamps in accordance with EDISON'S specification. Experts representing both sides of the case are to watch the process, and a report is to be presented to the judge by an independent witness.

The Barbadoes Cable.—The cable between St. Vincent and Barbadoes, which was recently interrupted, is now repaired.

Notice of Removal.—The Midland Electric Wire Company have removed their factory to Braunston Gate, and their address for the future will be "Faraday Works," Braunston Gate, Leicester.

Electric Railways in Japan.—It is stated that the Mikado has commissioned an engineer to visit the United States to gain information with the view of introducing electric railways into Japan.

Wolverhampton.—We are pleased to hear that Messrs. Elwell-Parker have been compelled, owing to the rapid increase in their business, to build two additional shops, and to put down a large extra engine to meet the increased demand for both dynamos and accumulators.

Reported Amalgamation of the Edison and Swan Companies in France.—The amalgamation of the Edison Continental Company with the Swan Company, so far as the French patents are concerned, has been announced. This union will, of course, put an end the litigation between the two companies in that country.

The Gibson Storage Battery.—We have received a pamphlet from the Gibson Electric Company of New York, from which we learn that the Gibson storage battery possesses an efficiency of 90 per cent. (!); that it requires no skilled attendance; that no possible rate of discharge can injure it; and that as to durability "it is practically indestructible." Hem!

Electrical Heating.—The Union Electric Railway Company, of Richmond, U.S., are now heating their offices by means of the Burton electric heater. With a current of 1·75 ampere and an E.M.F. of 300 volts a room of 15 feet square is efficiently warmed. It is the intention of the railway company to heat all its cars by this means during the ensuing winter.

The Paris-Marseilles Telephone.—On the 14th May, the first words were spoken over the new telephone line between Paris and Marseilles, which is shortly to be opened to the public. Excellent results were obtained, and conversation was easily carried on. The wires are of copper, and in diameter 4·5 mm., and the total length of the line is 900 kilometres (562½ miles).

Mouldings.—Mr. Samuel Elliott of the "Albert" Moulding Mills, Newbury, sends us a book of designs of wooden cleats, and mouldings, &c., in great variety. This firm is well known for the excellence of its designs in all classes of woodwork of this description, and electrical contractors will find it worth while to examine the price list and designs for cleats and mouldings.

Blair Lodge School Installation.—Blair Lodge School, near Falkirk, will soon possess a complete electric light installation of 700 lamps. Messrs. M'Whirter, Ferguson and Co., of the Faraday Works, Govan, are the contractors. In addition to the electric light there is telephonic communication throughout the school buildings. We believe this is the only school so provided in the country.

Freemasonry.—At a meeting of the Electric Lodge on the 26th ult., held at the "Mitre Hotel," Hampton Court, Mr. Thomas Barlow, Assistant Controller of the Central Telegraph Office, was installed Worshipful Master for the ensuing year, and Mr. James Hookey, the outgoing Master, was presented with a very handsome Past-Master's jewel on his retirement from the Chair.

New Cable to Ireland.—A new cable is being laid between Scotland and Ireland. Her Majesty's ship "Monarch" is in Belfast Lough with the cable on board, but the weather has been very unfavourable. The cable will be laid from Whitehead, on the county Antrim side of Belfast Lough, to Portpatrick. After the "Monarch" has completed her task, she will proceed to the Shetland Isles.

Electric Lighting Tenders Invited.—The Ilfracombe Local Board invite tenders for the lighting by electricity of the Victoria Promenade. Particulars may be obtained from the surveyor. Hotels and other establishments in the neighbourhood contemplate taking the light jointly with the above.—The Poole Town Council invite tenders for lighting the borough by gas, electricity, or other means, for one or three years from 1st September next. Particulars may be obtained from the town clerk.

Digitized by Google

Messrs. Whittaker's Forthcoming Publications.—The third edition of Sir D. Salomon's book on the "Management of Accumulators" having sold within a few months, Messrs. WHITTAKER will publish next week a new thoroughly revised and enlarged edition. They will also publish a second edition of "Leland's Practical Education," and a second edition of "Bottone's Electrical Instrument-Making for Amateurs," enlarged by a chapter on the telephone. They hope to have Mr. Preece's large work on "The Telephone" ready during next month.

Yokohama.—The electric light has been introduced into Yokohama by Messrs. Cocking and Co., of 55, Main-street, who have laid down a Gülcher plant. There is already in existence an Electric Lighting Company in Tokyo, chiefly, we believe, in the hands of natives, and they have recently applied for permission to establish a central station at Yokohama The local Gas Company are also anxious to go into the business on their own account. Mr. Cocking has, however, forestalled his competitors, and as an Englishman—and also we believe a thoroughly competent electrician—we trust that his enterprise will be successful.

City and Guilds of London Finsbury College.—The annual *conversazione* of the above college was held on Friday last, and may be pronounced as the most successful yet given. The lecture by Prof. S. P. Thompson on the Polarisation of Light, and that by Prof. Perry on Magnifying Springs, were extremely interesting. Two concerts were given in the Chemical Lecture Theatre; there was an extensive display of electrical, mechanical and chemical apparatus, including several novelties, and, finally, the second Annual Exhibition of the College Photographic Society. The attendance numbered 450. We intend to give some further particulars next week.

Hamburg Central Electric Lighting Station.—The firm of Mr. S. Schuckert, of Nuremberg, has been entrusted by the State of Hamburg with the installation of the Hamburg Central Electric Lighting Station, for which about twenty-four prominent firms have tendered. The central station is intended to supply about 20,000 incandescent lamps and an enlargement is in contemplation. During the course of this year a first installation of 10,000 lamps will have to be completed. According to the calculations issued by the Finance Committee it is expected that the undertaking will prove a financial success, 6 per cent. on the capital invested being the estimated net profits.

Paterson and Cooper's Instrument Catalogue.—Messrs. Paterson and Cooper have issued a new illustrated catalogue of their well-known electrical measuring instruments. Most of our readers will be already aware that this firm manufacture ammeters and voltmeters under the patents of Capt. Cardew and Profs. Ayrton and Perry, as well as a serviceable "engine-room" instrument of their own design. The improvements which have from time to time been introduced by Messrs. Paterson and Cooper in these various instruments have been fully described in our columns (see *Electrician*, Vol. XIX., p. 270; Vol. XX., p. 220). The present catalogue is well printed and illustrated, and gives ample information on all the subjects referred to. In addition to the various types of ammeters and voltmeters, it also includes the Thompson and Starling "Universal" photometer, and Mudford's improved Thomson galvanometer.

The Schuckert Projector.—The Schmidt Douglas Electric Company have lately been astonishing the inhabitants of Bradford by a fine display of electric light from the top of their premises at Hustlergate. The plant furnishing this powerful light has been manufactured by M. Schuckert, of Nuremberg. It consists of a projector with a horizontal arc, taking 150 amperes and 50 volts, and regulated both automatically and by hand; the lamp is furnished with a parabolic silvered-glass reflector, 3ft. in diameter, constructed to be movable in all directions; the whole apparatus with iron case, glass protector and stand weighs 7 cwt. The carbons used are made by M. C. Schmelzer, of Nuremberg, the positives being 1¾in. and the negatives 1¼in. in diameter. This apparatus has been adopted by the German Government for use in the Imperial Navy, and a portable field plant has been specially constructed for the Italians at Massowah.

Trial of a Police Signal System.—We are glad to learn that the police of London are about to be afforded an opportunity of experimenting with a system of electric communication between the police stations and certain fixed points on the beats of the men. The system adopted is that of the "Public Safety Signal Association." Sir Charles Warren has authorised the trial on condition that it involve no expense to the Metropolitan Police Fund, and has selected Islington, with headquarters at the Upper-street Police-station, for the scene of operations. The Vestry has conveyed its formal consent to the erection of the required apparatus in the district, and the Postal Telegraph Department has undertaken to run the necessary wires. As soon as these can be laid, the system will be put in operation and continued for three months at the expense of the association, during which time its value will be thoroughly tested. The experiment will involve a total outlay of some £1,200.

Breakdown in Paris.—On the evening of Sunday, 20th May, about eleven o'clock, the electric light suddenly failed at the Opéra Comique, and also in the Châtelet Theatre. Anything that came to hand was immediately lighted, candles, oil-lamps, and gas jets. Fortunately, owing to the recent introduction of the electric light, communication with the gas-mains had not yet been cut off. The cause of this failure was simple enough. Four machines, two large and two small, running in the basement of the Châtelet Theatre supply the current for the two buildings; of these, three are used every day and the fourth is in reserve. On Sunday evening the bearings of one of the dynamos began to heat, and it became necessary to stop running and start the reserve machine, and during this stoppage (owing to the inadequacy of the accumulators) the light went out. *L'Electricité* pertinently asks if it is not possible to guard against such a breakdown as this. The contracting company assert that if they had been allowed to run a double pair of mains they would have been able to have immediately restarted the light.

Fatal Accidents to Electric Light Linemen in Halifax, N.S.—Captain H. E. Rawson, R.E., writes from Halifax, N.S, as follows:—"I have forwarded by this post some local papers, reporting a coroner's inquest on the death of an electric light patrolman, who was killed on a pole which he had mounted in order to see to the light. The facts excited considerable interest, as it was the second death on the same pole within forty-eight hours. In the first case very little evidence was taken at the inquest; but it appeared that the man had crossed his leg over the cross arm, and was not touching the lamp, when 'blue fire' was seen under his thigh. He fell back, and was found badly burned between the legs and on one hand. The second case was taken up by the authorities, who applied to the general officer commanding to allow me to make a careful test of the lamp and its attachments. The Ball lamp is manufactured in Toronto. I have corrected the errors in the newspaper reports, which I think will interest you." We fear that the chief part of the papers sent by our correspondent have

Digitized by Google

been lost in the post. One paper has reached us, but it contains only an unimportant portion of the evidence.

Masters' Anti-Magnetic Watch.—We have had one of these watches in our possession for several weeks, and have subjected it to a series of very severe tests, with results of an exceedingly favourable character. The watch is provided with a gold balance and a hair-spring of palladium; the escapement contains no steel with the exception of the pallets. After being placed in the strongest part of the field of a powerful dynamo, which must have magnetised the whole of the steel parts to saturation, we found that the rate of the watch remained unaffected; and this, notwithstanding that for the succeeding three weeks it was continuously subjected to the influence of magnetic fields of varying intensity. It should, however, be noted that this watch, in common with all others, is brought to rest in a sufficiently powerful field, the reason being that the spring cannot do work against the Foucault currents which are generated in the balance-wheel. We do not know that the reason for this effect has been pointed out before; but it will be seen that so long as the rapidly-moving parts are made of metal it will be impossible to overcome it. This defect is, however, of small importance, as it causes no error in the rate of going of the watch.

Exeter.—At the last meeting of the Exeter Town Council the Special Committee on Electric Lighting recommended that tenders be invited by advertisement for lighting a specified area by means of the electric light, subject to the terms of the specification prepared by the surveyor and to the stipulation of the Board of Trade.—Mr. Townsend moved the adoption of the report, and said that when the tenders were received the committee hoped to lay before the Council a report as to whether it was desirable to proceed further, or whether they should continue the present system of gas lighting.—Mr. Jones seconded the motion.—Mr. Dunn said that to ask for tenders before the Council decided whether they would adopt electricity was not treating the persons who went to the trouble and expense of tendering with proper consideration.—Mr. Daw (interposing) said he should save Mr. Dunn the trouble of speaking any longer by leaving the Chamber, when there would no longer be a quorum.—The Mayor: There is another councillor coming.—Mr. Hall, who had gone outside, was returning to his seat as Mr. Daw was leaving his. On learning, however, that the subject under discussion was a proposal to advertise for tenders for the electric light, he at once took up his hat and left again, amid much laughter. The Council then broke up for want of a quorum.

The Conductivity of a Vacuum.—M. Foeppl, in *Wiedemann's Annalen*, gives the results of some experiments *apropos* of this vexed question. M. Edlund, in maintaining his theory, claims to have recognised phenomena of a luminous character, even when the vacuum has become so perfect as to prevent a visible discharge between the electrodes. M. Foeppl has studied the currents of a secondary closed circuit, actuated by an induction coil. This first was formed on a glass tube 7 millimetres outer and 4·2 millimetres interior diameter, and was composed of two layers of 18 turns, having an outer diameter of 67 millimetres. The electrodes of this glass coil were connected to the two ends of a second coil, also on glass, so arranged as to form a galvanometer, within which was placed a circular mirror magnet, suspended by a fibre of cocoon silk. The primary coil was 24 centimetres in length, 7·1 centimetres inner and 15·3 centimetres outer diameter, and was composed of 12 layers of 72 turns of copper wire 22 centimetres diameter, without the insulation. With this apparatus, and a current of 22·5 amperes, M. Foeppl could not discern the least movement of the needle, either on closing or opening the circuit. Neither could he discover the least phosphorescent light in the glass coil, with large range of rarefaction. The specific resistance of a vacuum, as shown by mathematical calculation, is at the least 48,000 times that of mercury, or about 3,000,000 times that of pure copper.

The British Association.—At the fifty-eighth annual meeting of this association, which will begin at Bath, on Wednesday, September 5th, the president will be Sir Frederick J. Bramwall, D.C.L., F.R.S., M. Inst. C.E. The local secretaries for the meeting will be Mr. W. Pumphrey, Mr. J. L. Stothert, M. Inst. C.E.; Mr. B. H. Watts; and the officers of Section G (mechanical science) are:—President, W. H. Preece, F.R.S., M. Inst. C.E.; vice-presidents, W. Anderson, M. Inst. C.E., W. Shelford, M. Inst. C.E.; secretaries, C. W. Cooke, W. Bayley Marshall, E. Rigg, M.A., recorder. The first general meeting will be held on Wednesday, September 5th, at eight p.m. precisely, when Sir H. E. Roscoe, F.R.S., will resign the chair, and Sir F. J. Bramwell, D.C.L., F.R.S., M. Inst. C.E., president-elect, will assume the presidency, and deliver an address. On Thursday evening, September 6th, at eight p.m., a *soirée*; on Friday evening, September 7th, at 8:30 p.m., a discourse on the "Electrical Transmission of Power," by Prof. W. E. Ayrton, F.R.S.; on Monday evening, September 10th, at 8:30 p.m., a discourse on "The Foundation Stones of the Earth's Crust," by Prof. T. G. Bonney, D.Sc., LL.D., F.R.S. F.S.A., F.G.S.; on Tuesday evening, September 11th, at eight p.m., a *soirée*; on Wednesday, September 12th, the concluding general meeting will be held at 2:30 p.m. Excursions to places of interest in the neighbourhood of Bath will be made on the afternoon of Saturday, September 8th, and on Thursday, September 18th.

Atmospheric Electricity.—Prof. L. Weber describes in the *Elektrotechnische Zeitschrift* a very interesting series of experiments on atmospheric electricity. He erected two *insulated* conductors on the top of the Reisengebirge, but he says that, curiously enough, since these have been put up they have never been struck by lightning, although before their erection lightning flashes were continually occurring. He also made some kite and balloon experiments, in connection with which he goes at considerable length into the question of the effect of the conducting string in altering the electrical condition of the circumjacent air-layers, and also considers the effects due to a long conductor completely insulated from earth, and without discharging points; a similar conductor, with slight power of discharge along its whole length; an insulated conductor, with strong discharging power (*e.g.*, a flame) at the upper end; and other similar and more complicated cases. His kite-string was really a steel wire; the discharging points on the kite consisted of 400 needle-points. In other cases he had the tails of the kite made of silver-paper for the same purpose. The potential was measured by the length of the sparks, and the current with a galvanometer; the latter varied in general from ·07 to 2·5 microamperes. The potential varied generally from 3,000 to 10,000 volts. When thick clouds were overhead there were no appreciable sparks, the strongest sparks being obtained when the zenith was either quite clear or when cumulo-stratas clouds appeared. With potentials of 11,000 and 20,000 volts, currents of 4 and 8 microamperes were obtained. The original paper will well repay perusal by those interested in the subject.

"The Dynamicables."—The dinner of the Dynamicables on Thursday passed off very pleasantly under the presidency of Sir William Thomson, who, when a suitable stage of the proceedings had been reached, made a brief, but well-directed speech, which we have pleasure in reporting in full. It was

Digitized by Google

as follows :—"Gentlemen—You may smoke." The members were afterwards invited by the chairman to "recount their experiences," and this they did in a very entertaining manner. Prof. Forbes related a few of his experiences in the United States, whence he has returned positively charged with information on the subject of central station lighting work. He was followed by Mr. Swinburne, who described the sad fate of a young man who took to "mixed mathematics," and who eventually succumbed to something in the nature of a calculus. This amusing sketch was well received. An account of a visit to the Oerlikon works, and of the dynamos now being constructed there, was given by Mr. Kapp. Mr. Swan spoke of the good effects of the Electric Lighting Act, which he thought, although not by any means an unmixed good, had checked immature work, and Mr. Crompton and Prof. Fleming described some novel applications of electric lighting in connection with ballet dancing. A dramatically narrated ghost-story, from his own experience, was contributed by Mr. Macfarlane Gray, who vouched for its truth. "An angel's nose," was the subject of a communication from Major-General Festing; and Mr. Spagnoletti gave a capital rendering of "I cannot sing the old song now!" Amongst the company we noticed Sir David Salomons, Prof. Adams, Messrs. Garcke, Webb, A. Snell, Wollaston, Mordey, Albright, Heaphy, and Beaumont.

Electric Lighting Apparatus for Lighthouses.—A correspondent writes from Paris as follows :—"Messrs. A. de Méritens and Co. have just sent to Copenhagen two alternate-current magneto-electric machines, three Le Baron arc lamps, a current distributor, &c., designed for Hanstholm lighthouse (Denmark). All this apparatus is installed at the Copenhagen Exhibition. The machines are of the well-known De Méritens pattern, and of the same type as those supplied for Macquarie (Australia), Lizard (England), the United States, Mikail and Berdiausk (Russia), Da Roca (Portugal), Tino (Italy), Dunkerque, Calais, Gris-Nez, La Cauche, Cayeux, Ailly, Fécamp, Creac'h (Isle of Ouessant), Les Baleines, Planier (France). At St. Catherine (Isle of Wight) and Isle of May (Scotland) the De Méritens machines are of the largest size hitherto made. The Le Baron arc lamp is specially constructed for very large alternate currents, 300 to 400 amperes, but works quite satisfactorily with the very small amount of 25 to 50 amperes. The upper and lower carbon-holders are balanced by chain and train of wheelwork, and the movement is regulated by a solenoid connected in shunt. The current goes direct to the lower carbon by a very good sliding contact, preventing injury to the lamp from heating. When the carbons are burnt, the circuit of the coils is broken mechanically. All its functions are automatic, and the adjustment of the arc is so that it remains unchanged in position or size, the regulation being absolutely independent from the weight of the carbons. Whatever the current may be, the result is all that can be desired as regards steadiness and regularity. The current distributor consists of horizontal brass plates upon a polished mahogany table. These plates are connected with the terminals of the magneto-machines. Two vertical bars at the back of the table can be jointed with plates by means of screw plugs. Thus, currents of 60, 120, 180, 240 amperes can be utilised by turns in the lamp above described. These novel features have been chosen in France, where a current of 25 amperes is to be used in very clear weather, and currents of 50, 75, 100, or more amperes, according to atmospheric conditions, with the same machinery."

United Kingdom Postal Telegraph Clerks' Association.—The seventh annual conference of this association was held at the Green Dragon Hotel, Leeds, on Saturday. The delegates had been entertained at dinner by the Leeds staff on Friday evening, and the conference assembled on Saturday morning. Delegates were present from nearly all the large offices in the United Kingdom and from many of the smaller ones. Mr. T. C. Plackett (Leeds) was elected chairman. He gave a cordial welcome to the delegates, and trusted that their deliberations would be marked by that spirit of moderation which was essential to success. They were met together to discuss matters of vital importance to their organisation, and he hoped they would arrive at such decisions as would ensure the soundness and stability of the society. With reference to the redress of grievances, they were bound to admit that many of the grievances which had been complained of in former years had been remedied, that valuable concessions had been made, and that in no grudging spirit. But there were still questions unsettled, however, and he asked them in dealing with these matters to exercise a wise discretion, and to see that that respect was paid to others which they themselves expected.—The annual report for the year ending the 3rd of May was read by Mr. Scott (Liverpool), which showed that the association was in a very much improved financial condition, the balances in hand having increased very considerably. The numerical condition of the association was practically unchanged. The report on the whole was favourable. —A proposal by the Birmingham members, introduced by Mr. Whittall, materially affecting the insurance branch, and proposing a lower rate of insurance benefit, was warmly discussed, and after nearly three hours' debate was adopted with certain modifications.—A resolution in favour of forwarding a united petition to the Postmaster-General on the subject of unredressed grievances was negatived, it being considered desirable that the statement of affairs which has been placed in the hands of the Civil Service Commissioners should not be supplemented by any other petition which would be likely to imply a want of confidence.—A resolution from Leeds, proposed by Mr. Richardson, and seconded by Mr. Clarkson, was supported by delegates from Hull, Preston, and Southampton, and eventually carried as amended—"That the present scheme providing for annual leave of absence is unsatisfactory and unacceptable as a settlement of the holiday question." Mr. Taylor (Bristol) called attention to the progress of the agitation in favour of Sunday pay, and read letters from several members of Parliament who have promised support in the House of Commons. It has been arranged that this matter shall be brought forward on the Estimates. A resolution was adopted expressing the appreciation of the conference at the energetic action of the Bristol staff, and pledging the support of the association. Several resolutions were proposed making alterations in the rules of the association, and after discussion agreed to. A resolution was adopted conveying the thanks of the conference to the editor of the *Telegraphist* and the press generally for their advocacy of the claims of the clerks. The following officers were elected for the ensuing year :—Trustees, Mr. Whittall (Birmingham), Mr. Rickwood (Manchester), and Mr. Scarborough (Belfast). The general secretary, Mr. Scott (Liverpool), was re-elected unanimously, with Mr. Hoolihan (Liverpool) deputy-secretary. On the invitation of the Bristol staff it was decided to hold the 1889 conference in that town. After a vote of thanks to the chairman and to the members of the Leeds staff the conference terminated. The delegates were afterwards driven to Roundhay Park, where they spent an enjoyable evening. By the courtesy of the Postmaster and Superintendent of Telegraphs at Leeds the delegates were permitted to inspect the Leeds office.

CONTINUOUS-CURRENT TRANSFORMATION.

(*Concluded from page 734, Vol. XX.*)

BY R. PERCY SELLON.

Lane-Fox's Patent of July, 1883, is followed by that of Scott and Paris, No. 6,260, of April, 1884. This patent also has reference to the broad question of distribution by means of continuous-current transformers. It deals with the placing of these in parallel, both as regards their high-tension and low-tension circuits, and a claim is made to "the arranging of transformers, both in the high-tension and the low-tension circuits in parallel, so as to be independent of one another, substantially as hereinbefore described with reference to the accompanying diagram."

It will thus be seen that this Patent differs from the preceding Patents of Edison and Lane-Fox in respect of the suggested disposition of the primary circuits of the transformers in parallel.

Messrs. Scott and Paris have been closely associated with continuous-current transformers in this country for some time past, and they are among the very few who have been sufficiently inspired by the courage of their convictions to commit those convictions to the test of practice. It will be remembered that they showed one of their transformers at the Newcastle-on-Tyne Exhibition last year, and this attracted some considerable amount of attention. Full descriptions of their system have appeared in this journal under the issues of October 28th and December 2nd of last year, and it is therefore unnecessary to refer at greater length to it at this point.

Three months later, Zipernowski and Déri took out a Patent, No. 9,982, 1884, upon this subject.

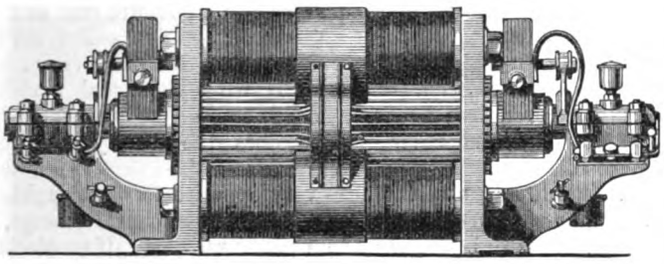

Fig. 1.

This specification is a very full one, and deals with the application of continuous-current transformers [or "rotating secondary generators," to use the patentees' words] to a variety of purposes—lighting, motive power, electric traction. Means for externally regulating and controlling their speed or output, and for measuring the work done, are also set out at some length.

The claims, however (which are 18 in number), would appear to indicate that this Patent was filed in ignorance of what had gone before upon the subject.

Patent No. 3,525, of March, 1885, R. P. Sellon and J. S. Sellon, follows that of Zipernowski and Déri. This Patent deals with various methods of winding and connecting up continuous-current transformers, in order to obtain automatic self-regulation. Where the conditions of supply are to be those of constant potential, the transformer-fields are to be compound wound, a shunt winding to be connected with the "motor," or receiving armature coils, and a series compensating winding in connection with the "generator" armature coils.

The author turned his attention to the construction of continuous-current transformers in the year 1884, and about the period of the above Patent the machine illustrated in Fig. 1 was completed. Following this, negotiations were opened for lighting a town in South America by means of continuous-current transformers; but, for reasons unconnected with the technical aspects of the question, the matter was ultimately abandoned.

Cabanellas, in a Patent No. 2,880, of February, 1886, deals with improvements in continuous-current transformers. The specification is voluminous, and in the nature of a treatise upon details of construction of dynamo apparatus. The specification is, however, hardly sufficiently lucid to enable a strict definition of the nature of the improvements in continuous-current transformers to be set out.

In the following month Bollmann, Biedermann and Monnier patented (No. 3,945, March, 1886) a continuous-current transformer of a somewhat different type to the dynamo transformers which have been considered. The device consists of a series of stationary ring or closed-field magnets, divided up into two separate circuits. By means of an independent commutator, to which revolution is imparted in any convenient way, such as by an electro-motor or shafting, the connections of the two circuits are alternately changed. Thus, at one moment the primary current is passing through one set of magnet coils in series, thereby inducing a current in the second set of magnet coils, which are momentarily connected by the commutator in parallel, with the result of producing a current of diminished tension and increased volume in the supply circuit.

Upon the revolution of the commutator the functions of the two circuits are reversed. In this way the primary and secondary currents flow successively in each circuit, but always in the same direction. It will be seen that this is, therefore, an intermittent current transformer.

There is a subtle fascination about this idea that has "bitten," to the author's knowledge, more than one electrician in this country. The barrier to success, however, disregarding all outside considerations, seems to lie in the wear and tear arising from sparking in this class of apparatus. Messrs. Bollmann, Biedermann, and Monnier wrestle with this difficulty in their specification, but how far successfully in the practical outcome it is not easy to forecast. The author's scepticism arises out of the fact that he also believed himself to have "discovered" this idea some years ago; but his enthusiasm was cooled at the very spot indicated, viz., that at which the heating and sparking were found to result on trial.

Following the above, we have the Patent of Jehl, No. 2,130, of February, 1887. The work of Messrs. Jehl and Rupp, and many of the ingenious and carefully thought out designs suggested by them for continuous-current transformers have already been described at length in this journal, under the issues of October 28th and November 11th of last year.

It is therefore unnecessary here to do more than record the existence and date of Jehl's Patent, and to mention that the forms which have been described in this journal are to be found, and in some cases are claimed, in the above Patent.

Finally, in Patent No. 6,682 of May, 1887, Mr. James Swinburne addresses himself at some length to the problem of continuous-current transformers. The specification deals principally with means for attaining self-regulation, or "compounding," the transformers, which it is proposed to effect under certain conditions by using two separate sets, both of armatures and field-magnets, and adapting special windings to these. In this way also, says the patentee, the difficulty of leakage between the high and low tension windings may be effectually obviated.

This concludes the substantial history of continuous-current transformation up to date. The dominant feeling left in the mind after a careful perusal of all the Patents referred to is one of unmingled astonishment at the system upon which the average patentee goes to work. He glories, apparently, in drawing up his Final Specification and Claims with a cheerful disregard of the state of public knowledge up to date, despite the fact that he has had the better part of a year in which to make himself acquainted with it before drawing up the Final.

The net result is to be seen, and felt, in much subsequent heartburning, concurrently with litigation of the order with which we are just now only too familiar.

The fact that several gentlemen have been more or less patenting the same thing—or, at any rate, the same thing with microscopic differences—is purely a personal matter, however, and does not affect the main question which impresses itself upon one—that a large amount of careful thought has been already expended upon continuous-current transformation, which should bear good fruit when the opportunity for practically testing the system arises.

Digitized by Google

The practical application of continuous-current transformers is not surrounded by the same difficulties from within as would be the case where apparatus involving totally novel principles or combinations of physical laws might be concerned. The dynamo is sufficiently well understood to enable us to forecast with considerable precision where the difficulties with continuous-current transformers would arise for the purposes of electrical distribution; and while it is in the very nature of things that there will be, and ultimately must be, departures from the accepted ideas for the ordinary dynamo machine when dealing with continuous-current transformers, those departures will not be fundamental, but merely in matters of relative detail.

The author has reason to hope that before long some such practical outcome may be looked for.

ON THE TRANSMISSION OF ELECTRICAL POWER APPLIED TO RAILWAYS.

BY H. COERPER, OF COLOGNE.

The employment of electrical propulsion for cars is more and more drawing to the front. In America there are already electrical railways at work in not less than twenty towns, while on the Continent several lines have been in operation for some time.

Now, whether the electrical energy be supplied from outside or by means of storage batteries placed in the car, there are three distinct questions to solve. In the first case we have to consider the most suitable form of motor, the most reliable kind of transmission between motor and car, and the best mode of supplying the current. In the second case we have to ascertain what is the best accumulator, the best motor, and the best gearing. The mode of supplying the current to the car will not be considered here, a few remarks on the motor, accumulator, and gearing only being made.

Up to the present time high-speed dynamos of the most varied construction have, as a rule, been employed as motors, their power being transmitted to the axle by means of toothed wheels, friction wheels, belts, chains, wire spirals, worm gearing, &c. Immisch and Holt fasten the motor to the axle of the car, the wheels running on collar-boxes; one wheel is connected with a toothed crown wheel, into which fits the small tooth wheel on the axis of the dynamo. This gearing did not answer, however, and a new method is now tried. A satisfactory solution of the matter has not yet been arrived at, owing principally to the very nature of the thing. It is very rarely possible to count on uninterrupted runs of definite duration in the case of tramways; when it *is* possible to do so, arrangements may be made such as are in force on the line near Schwabing. At the terminus the car runs up an incline 18 metres long, it is stopped at the top, and on restarting downwards attains a great speed before it is necessary to switch on the motor. In most cases, however, such an arrangement is impossible, because the car is frequently obliged to stop and restart, without any regard to the construction of the line, so that the motor is often called upon to make the greatest effort under the most unfavourable circumstances. A firm coupling between motor and axle is mechanically indispensable. Trials on a line perfectly level and in the best condition have now proved that a car which will obtain a velocity of 5 metres per second (11 miles per hour) with a traction force of 120 kilogramme-metre-seconds (1·6 horse-power) requires 345 kilogramme-seconds (4·6 horse-power) to start. With the line in a worse state, and with curves, inclines and uneven loads to contend with, the relation becomes even more disproportionate.

In order to comply with practical working requirements, the motor ought, therefore, to develop the maximum power when starting. This, however, with all motors hitherto devised is not the case. On starting, when the current is switched on, the motor, owing to its firm coupling to the axle, starts but very slowly. The current, although so excessive as to endanger the insulation of the motor and cause great sparking on the commutator, develops in the motor but a small fraction of the power which it develops when working under normal conditions, and only when the car has attained a certain speed does the motor work under the best conditions, which is, however, when the heat power is necessary. Another drawback to the present arrangement is the mode of transmitting the power from the motor to the axle. Worm gearing, tooth gearing, &c., all cause great loss of power, as is shown by the rapid depreciation of the working parts. Belts, wire spirals, &c., also cause a considerable loss of energy. The higher the speed of the motor the greater does this loss become. We have further to take into consideration the inferior safety of the ordinary arrangements. Breakdowns are of frequent occurrence, and the expense of repairs is considerable. Unfortunately it is the electrical arrangements which are generally blamed for these interruptions, and not the defective mechanical arrangements.

Resuming, we find that under present conditions the motor works under the most unfavourable circumstances when starting; that it has the least power when it requires the most; that it develops the greatest power when it requires the least; that the gearing and belting entail a considerable loss of power; and, finally, that the mode of transmission is unsafe, expensive, and detrimental.

If accumulators furnish the motive power, then we must take into account the frequent damage they are exposed to. An accumulator is almost indestructible if properly charged and discharged, and every possible effort has been made to fit them for tramway work; rather unreasonably, however, since any good accumulator will do if not over-worked. As long as the present type of motor is used overstrains must necessarily occur. Nothing hurts an accumulator more than a short circuit; yet this is what practically happens every time a start is made, the current being only moderated by the copper resistance of the motor, and not by the counter E.M.F. In the present state of technical science it is an easy matter to construct an accumulator equal to a 50-kilometre run and to place it on a car, but it is a thoroughly useless endeavour to try and make an accumulator to stand 50 to 100 short-circuits in a 50-kilometre run. Yet this is what the usual working conditions require; hence, as the dynamo gets overheated by these constant short-circuits, so does the battery get over-strained.

All these circumstances, the very opposite to what ought to be, point with irresistible force to a fundamental change, if the future is to belong to the electric railway. If no electric railways existed the engineer would probably propose the following conditions:—

(1) The motor to develop the maximum power on starting.

(2) The transmission of power from motor to axle by means of worm gearing, &c., is inadmissible on account of the great wear and tear, the insecurity of the working, and the loss of power.

(3) Neither accumulator nor motor must be exposed to short-circuits, because they destroy the accumulator and endanger the motor by overheating and sparking on the commutator.

With a view to embody these *desiderata* the arrangements shown in Figs. 1 and 2 have been adopted by the Helios Company. The magnetic field *c* of the motor is fixed upon the propelling axle itself, so that the turning of the magnetic field involves the turning of the axle of the car. The armature shaft *a* and the brake wheel *e* are placed on the hub *f*, which is mounted upon the axle by means of collar boxes. The magnetic field carries brushes mounted on the spindles *g g*, which bear upon the commutator *h*. The latter is mounted upon the armature shaft and is also attached to the brake wheel. Upon the hub of the brake wheel are two contact rings, *i i*, by which the current is conducted to the armature coils. Upon the other side of the shaft at *k k* there is another pair of contact rings by which the current goes to and from the magnetic field. Upon the magnetic wheel *b* and the brake wheel *e* there is the speed-reducing gear *l m*, which is regulated by a lever, *n*. If the lever *n* is turned towards I then by pushing the brake block *m* against the brake wheel *e*, the brake wheel and armature are stopped, and *vice versa*. When the lever *n* is turned towards I I the wheel *b* is stopped, the brake wheel *e* and the armature are freed. According to very accurate trials made by myself, a properly constructed motor makes, with uniform

Digitized by Google

supply of current and the same output, the same number of revolutions, no matter whether the magnetic field or the armature is made to turn. If armature and field are left to run simultaneously in opposite directions, each makes half the usual number of revolutions. If, therefore, the propelling axle *a* rests in the bearings *o*, we can by braking the armature cause the field alone to exert the propelling power, or, by merely moderating the speed of the armature, we can give a proportionately lower velocity to the magnetic field and consequently to the axle of the car.

The effect of the above arrangement is as follows:—When the car stops the brake must have been applied to the car-wheel, thus liberating the brake-wheel *e* and the armature. If the circuit is now closed the armature at once attains its normal speed, preventing a short-circuit of either motor or accumulator. To start the car the conductor must free the car-wheel, thereby braking *e* and the armature *d*. In proportion, however, as the speed of the armature is reduced, that of the field increases, so that finally, when the brake-block *m* completely stops the wheel

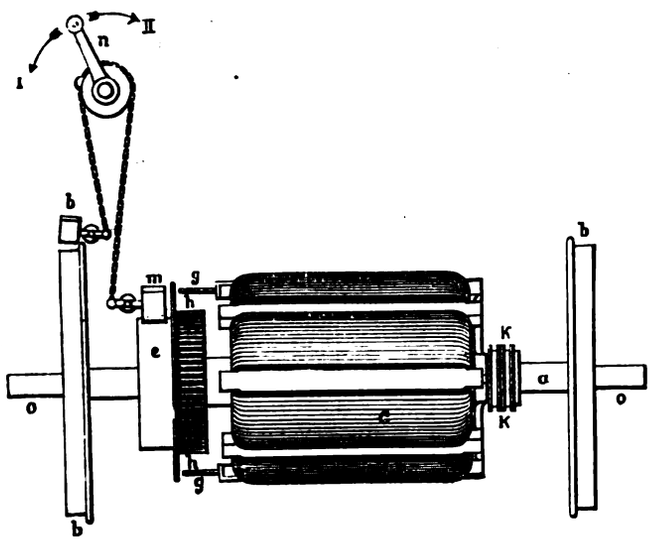

FIG. 1.

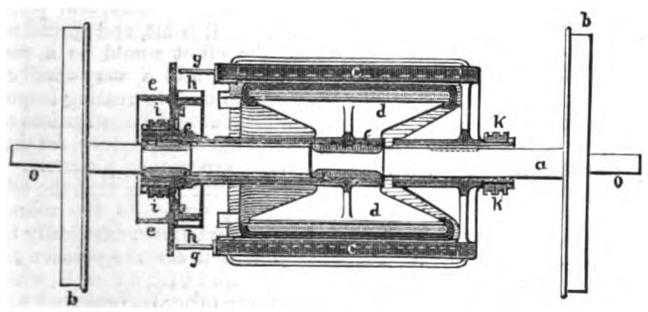

FIG. 2.

e, and with it the armature *d*, the magnetic field *c* alone propels the car. To stop the car, the lever *n* is turned towards I, the armature is freed, and, having no power to exert, at once runs at the normal velocity, whilst the tractive force of the field ceases, and the brake can immediately arrest the motion of the car.

It is clear that the braking gear can be varied, the predominating idea of this arrangement always remaining the same, viz., the firm connection of either armature or field to the propelling axle, and the freely movable arrangement of the other, controllable by a special braking gear. The direction of the motion is controlled by the direction of the current.

Let us now examine how far our list of necessary conditions has been complied with.

1. The motor attains its normal velocity instantly the circuit is made, even if the car is at rest; so that it develops its maximum power at the moment of starting.

2. All gearing is dispensed with by fixing the motor upon the axle.

3. Neither accumulator nor motor is short-circuited on starting, because before the car can move the brake has to be taken off *e*, allowing the armature at once to assume its normal velocity.

Objection may be made to the moving brushes and to the necessarily slow speed of the motor, involving an inferior efficiency. The first objection is pointless, since whether the brushes are fixed or movable they could not be adjusted whilst the car was in motion. The second objection brings us at once face to face with the electro-technical dogma that "slow-speed machines are less efficient than high-speed ones." I always ask, what machines these are? The slow-speed machines built by the Helios Company at Ehrenfeld according to my specification, and running at from 80 to 120 revolutions a minute, all possess an electrical efficiency of over 90 per cent. When running the machines hardly get warm, the current density in the coils being never greater than 1 to 15 amperes per square millimetre sectional area. Run off Helios engines of 80 or 100 horse-power our dynamos, when fully loaded, give a very high number of watts per indicated horse-power. There are, however, many difficulties in the way of testing machines when not loaded. I will therefore refrain for the present from giving a precise result of the effective horse-power. I maintain, nevertheless, that no high-speed machine gives a better commercial result. Measurements taken from a few small machines are, in my opinion, valueless.

As things are, the objections to slow-speed machines mounted on the axle apply only in the case of badly constructed motors. The arrangement, however, is quite unobjectionable when a properly constructed machine is used. In the present case a tramway motor is the object in view. The diameter of the wheels is 750mm., the circumference is therefore 2·35 metres. The car is to run 300 metres in one minute, hence the wheel makes 125 revolutions a minute. To do this we have a series motor with an electrical efficiency of 86 per cent. I hardly think that anyone, after an examination of the practical working conditions, would assert that this slow-speed machine gives an inferior commercial efficiency as compared with a high-speed machine, the power from which has to be transmitted to the axle by means of toothed wheels, worm wheels, chains, belts, &c.

I am of opinion that only the plainest views concerning the construction of machines can lead to practical solutions of electrical problems. The chief thing is to provide good mechanical arrangements. The wrangling over fractions is beside the point, especially if the public are left in the dark as to whether the efficiency claimed is merely a paper electrical efficiency or an actual commercial efficiency. Hence, I believe that the arrangements above described, avoiding, as they do by their simplicity as far as possible all the present defects of electrical railways, will further the introduction of electricity in this direction, notwithstanding academic considerations of efficiency.

NEW EXPERIMENTS ON THE ELECTRIC ARC.

Dr. Lecher, in the *Centralblatt für Electrotechnik*, No. 3, 1888, gives an interesting Paper on the above subject. Dealing first with the nature of the apparent resistance of the arc and the fact that it does not increase in resistance proportionately to the increase of distance between the carbons, he remarks that the theory of a counter E.M.F. was started by Edlund in 1867, and upheld more recently by Lang and Arons. Fröhlich and Peukert hold the same view in a modified form, and consider that only part of the apparent resistance is due to back E.M.F., and that the remainder is due to a resistance such as occurs at the electrodes of a Geissler tube. Wiedemann attributes the resistance to discontinuous discharge, and the author himself points out that the non-increase of resistance may be partly due to the fact that the arc spreads out and increases in cross-section when it lengthens.

An experiment mentioned affords strong evidence against back E.M.F., though founded on one of Edlund's to prove its existence. In the adjoining figure (Fig. 1) D is a dynamo, working an arc lamp, L; *g* is a permanent magnet ammeter, furnished with a stop, retaining the needle at zero when the current is in one direction, but leaving it free to move when reversed. The current is then switched on from the dynamo

Digitized by Google

in the direction to hold the needle against the stop. The switch A is then closed, short-circuiting the dynamo, and at the same time leaving a closed circuit through the arc and ammeter so that if there were any back E.M.F. it would move the needle away from the stop. An extremely slight movement *was* observed, but as just as much was obtained when B was closed instead of A, it could only be attributed to the spring of the needle. It may be suggested that the resistance between the carbons was so high that no current could pass. It was found, however, that this resistance did not increase very rapidly when the arc was extinguished. To prove this the primary of an induction coil was placed in the lamp circuit. When the carbons were suddenly torn apart a spark was obtained from the secondary; but if the carbons were fixed and allowed to burn out of themselves no spark was obtained, showing that the resistance increased but slowly on extinction.

In 1869 Edlund first expressed the E.M.F. at the terminals of the arc in the form $a+b\,l$, where a and b are constants, l the length of the arc, $b\,l$ being the simple ohmic resistance. The constant a may be either a back E.M.F., as Edlund considers, or may be due to a certain initial work done at the electrodes in maintaining the arc quite apart from the actual resistance of the arc itself.

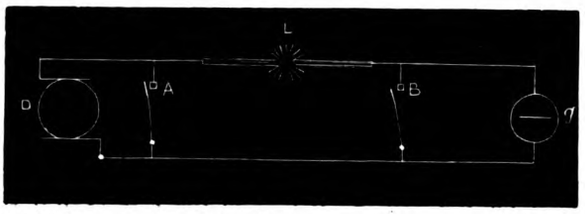

FIG. 1.

In order to see if the difference of potential of the arc is dependent on temperature, three series of tests were made—

1. With the carbons horizontal, and one heated with gas blowpipe.
2. Carbons horizontal, with the electrodes bound round with fine copper wire almost up to the arc, to conduct the heat away.
3. The electrodes vertical, the lower one sunk in a large mercury bath almost up to the arc, for cooling.

Difference of potential measured by electrometer current in all experiments 5 amperes, and, except when mentioned, the arc was 2 mm. in length.

In (1) the normal difference of potential was 42 volts; this rose to 48 volts when the positive, and 52 volts when the negative, was heated. These were the highest results obtained.

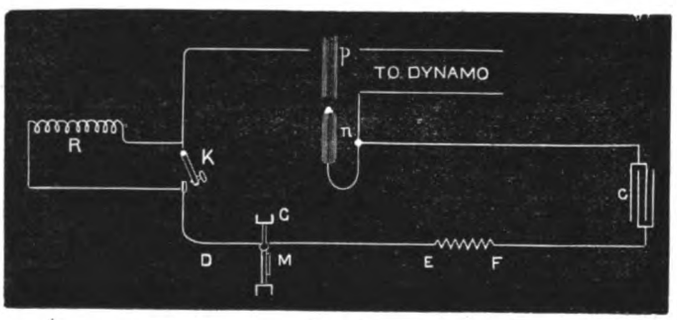

FIG. 2.

Much depends on the intensity of heat applied. If the carbons are vertical the upper one is warmed by the lower, and it was found that with the upper carbon positive the difference of potential was 47 volts, and with the upper carbon negative 46. If the lower carbon be cooled with mercury the difference of potential falls to 43 with negative below, and 41 with the positive below. This last figure was obtained by interpolation, as the arc could not be maintained steady at such a low difference of potential. The carbon in the mercury burnt to a blunt point instead of forming a crater or sharp point.

To represent the results in the form $a+b\,l$ we have

		a	$b\,l$	
Carbons horizontal uncooled...Difference of potential =		33	$+4{\cdot}5\,l\pm1{\cdot}5$	volt
,, vertical	,,	$35{\cdot}5$	$+5{\cdot}7\,l\pm1{\cdot}5$	,,
,, horizontal with copper cooling		25	$+5\;\;l\pm3$	,,

It is therefore evident that with carbon electrodes the difference of potential distinctly *is* affected by temperature; this will account for the fact that thick carbons, which remain cooler than thin, require a smaller difference of potential for a given length of arc.

With 5 mm. platinum electrodes (horizontal) the difference of potential was about 35 volts, with 2 mm. arc reduced by copper-wire cooling to 26 volts. For uncooled electrodes difference of potential $=28+4{\cdot}1\,l\pm1{\cdot}8$.

The results with iron electrodes 5·5mm. diameter were not very reliable;

$$\text{difference of potential} = 20+5\,l\pm3.$$

Difference of potential appeared to increase slightly with rise of temperature.

Copper electrodes, 4·4 mm. The temperature was already so low that only heating effects were tried. Difference of potential with 2 mm. arc about 26 volts, and rose about 2 volts when the electrode was heated (rather greater effects from heating negative than positive).

Silver electrodes, 4·9 mm.; horizontal, difference of potential = 20 volts, positive carbon heated 23 volts, negative carbon heated 28 volts.

With both silver and copper the results are very trustworthy, but in both $\frac{a}{b}$ appears to be comparatively small. With silver difference of potential appears to be about $8+6\,l$ volts.

A very possible explanation of the unsteadiness of the ordinary arc is that the point where the arc leaves the carbons becomes very strongly heated, the potential of difference rises, and the arc consequently keeps on moving to cooler parts.

INVESTIGATIONS ON THE INTERIOR OF THE ARC.

A pointed carbon rod, 1·5 mm. diameter, connected to one terminal of the electrometer, was introduced into the arc itself (2·5 mm. long), and the difference of potential thus taken between various parts of it and the carbons. It had been found by previous experiments that this had no appreciable effect on the difference of potential between the carbons.

The difference of potential between the + and − carbons was 46 volts. The difference of potential between the + carbons and *any* part of the arc differed but very slightly from 36 volts. The constant b, therefore, must be very small indeed, and could not be anything like 4, as above assumed, as this would have given a difference of about 10 volts, which could not have been overlooked. The total difference of potential appears to be made up of two—one of 36 volts at the hot + carbon, and one of 10 volts, not in the arc itself but at the cool − carbon.

With metal electrodes the E.M.F. of the arc itself lay very nearly half-way between those of the two electrodes, possibly because there was not nearly such a difference of temperature between them as between carbon electrodes.

The author here again refers to the fact that as the arc lengthens it thickens, so to speak, or increases in cross-section, and points out that if it left the carbons at a very small point, and spread out to a very great extent between them, the effect would be a very high resistance at the carbons themselves, and a very small resistance of itself, which would not increase with increasing length. The author then described some less satisfactory investigations on the discontinuity of the arc, the evidence being rather for than against discontinuity when the electrodes are iron or platinum.

It has already been found by other investigators that the telephone is not available for this purpose, owing to the minute fluctuations of the steadiest arc. Fig. 2 shows diagrammatically the method which Dr. Lecher adopted; p and n are the positive and negative electrodes; one of these is connected with a coil, R, which has a large self-induction coefficient; the other is connected with the condensers C and C^1. E F is a spiral spring, one end of which is attached to the terminals of the condensers, and the other end is fixed to a fine wire D E, which is connected with the coil R, and is kept stretched by the spring. This wire at its centre makes a turn around the steel axle G H, to which is also fixed a light mirror, M. It will therefore be seen that when the tension of the spring varies the mirror undergoes an angular deflection, and this is rendered visible by a beam of light reflected from the mirror in the usual way. The coil R is provided with a short-circuiting key, K, by which it can be cut out of the circuit.

Now, if the discharge between the electrodes is discontinuous, the fine wire D E will be traversed by currents of charge and discharge from the condensers; the wire will therefore be heated, and the contraction of the spring E F will cause the mirror M to be deflected, and the amount of discontinuity can thus be estimated. In the experiments with carbon electrodes and a condenser of one microfarad capacity, it was found that with the coil R short-circuited the deviation of the luminous ray reflected upon a screen placed at five metres distance amounted to 40 mm. when the arc was hissing.

The addition of a second condenser doubled the deviation. When the distance between the carbons was increased, the deviation diminished, and became zero as soon as the arc was silent. If while the arc is hissing the key K is opened, bringing the coil R

Digitized by Google

into circuit, the deflection immediately disappears owing to the attenuation of the current waves by the self-induction.

With electrodes of iron instead of carbon the deflection was produced even with a very long arc, but it diminished in proportion as the length of arc was increased. With platinum the phenomenon is still more marked. If the condensers are dispensed with the length of the arc can be reduced to any extent without producing these effects.

It is evident from these experiments that the oscillating charge and discharge of the condensers plays an important part, but they are on that account none the less interesting. It may be hoped that a further study of the phenomenon will throw light upon questions which are at present but little understood.

The author remarks in conclusion that of course quantitative experiments must be made before any definite result can be arrived at, but he claims that his qualitative investigation shows that—

1. There is no proof of back E.M.F. by any return current.
2. Difference of potential is affected by temperature.
3. If the negative electrode is platinum or iron the discharge is discontinuous.

EXPERIMENTAL CURVES OF ALTERNATING CURRENTS.

From a paper by Dr. Louis Duncan and Messrs. Hutchinson and Wilkes, in the *Electrical World* of New York, we reproduce the adjoining curves of alternating currents which have been experimentally obtained. Fig. 1 represents the current through the

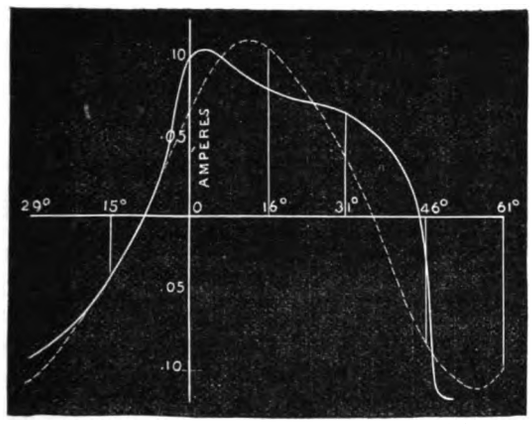

Fig. 1.

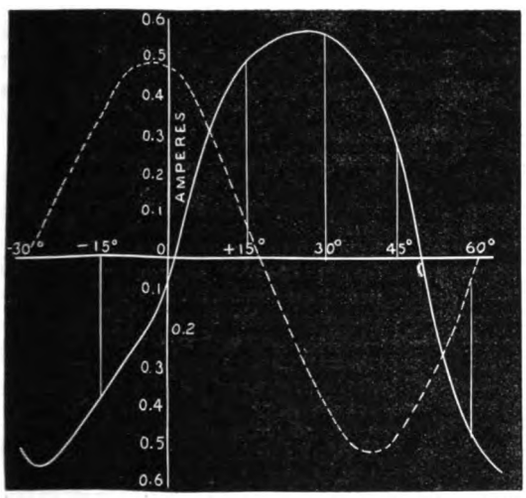

Fig 2.

primary coil of a Westinghouse transformer, and Fig. 2 is the corresponding current through the secondary. The method adopted for obtaining the curves is not given in the paper from which we copy them. The dotted curves represent sine functions; for the primary current the sine curve is drawn to the same maximum ordinate and so as to cross the axis at the same point; for the secondary current the sine curve is drawn in the position corresponding to that of the primary. The smoothing down of the irregularities of the primary is very marked in the secondary. But we fear that the shape of the primary curve does not say much for the design of the machine from which it is derived. Dr. Duncan, however, accounts for the form of the primary curve by saying that changes in the coefficients of induction—at different points on the curve—produce a considerable effect on the primary, while changes in the absolute values of the self and mutual coefficients, *provided they are in the same proportion*, do not greatly affect the values of the secondary. On this subject we may also refer the reader to a recent discussion at the Physical Society on a Paper by Mr. Sumpner, reported in our issue of April 27th, and to a Paper by Prof. Elihu Thomson in our issue of February 17th.

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, June 1st.

ROYAL INSTITUTION.

9 p.m. "Earthquakes and How to Measure Them." By Prof. W. DEWAR.

SATURDAY, June 2nd.

ROYAL INSTITUTION.

3 p.m. Lecture, "Count Tolstoi as Novelist and Thinker" (1). By Prof. C. E. TURNER, of the University of St. Petersburg.

MONDAY, June 4th.

ROYAL INSTITUTION.

6 p.m. General Monthly Meeting.

TUESDAY, June 5th.

ENGINEERING SOCIETY (King's College, London, W.C.).

4:15 p.m. Paper on "Transformers." By Mr. PREECE.

ROYAL INSTITUTION.

3 p.m. Lecture, "Conventions and Conventionality in Art" (3). By Mr. SIDNEY COLVIN, M.A.

THURSDAY, June 7th.

SOCIETY OF TELEGRAPH-ENGINEERS.

Students' Meeting. Paper on "Belts and Belt-Driving for Dynamos." By Mr. J. N. COOPER. Prof. J. PERRY, D.Sc., F.R.S., in the chair.

CHEMICAL SOCIETY.

8 p.m. Meeting.

ROYAL SOCIETY.

4 p.m. Meeting. Election of Fellows.

ROYAL INSTITUTION.

3 p.m. Lecture on "The Growth and Sculpture of the Alps" (3). By Prof. T. G. BONNEY.

FRIDAY, June 8th.

ROYAL INSTITUTION.

9 p.m. Lecture on "Phosphorescence and Ozone." By Prof. DEWAR, M.A., F.R.S., M.R.I.

SATURDAY, June 9th.

ROYAL INSTITUTION.

3 p.m. Lecture, "Count Tolstoi as Novelist and Thinker" (2). By Prof. C. E. TURNER.

PHYSICAL SOCIETY (Normal School of Science, Exhibition-road, South Kensington).

3 p.m. "On the Analogy between Gases and Substances in Dilute Solutions." By Prof. J. H. VAN 'T. HOFF. Communicated by Prof. W. RAMSAY. Exhibition of a Lantern by Mr. W. LANT CARPENTER.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Hernosand Central Station.—A correspondent writes as follows:—"The town of Hernösand, Sweden, one of the first towns in Europe in which the streets were lighted by electricity, has now under contemplation extending this mode of illumination to house lighting. The cost of a central station with motive power has been put at 42,000kr.; the annual expense has been calculated at 8,000kr., and the revenue at 14,000kr. The corporation will probably take the matter in hand."

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to The Proprietors.

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"The Electrician" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

"The Electrician" in America.

"The Electrician" *can be obtained in America from* D. Van Nostrand, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"The Electrician" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

The Proprietors *of* "The Electrician" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued The Electricians' Directory and Handbook. *The* Directory *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

THE MUNICIPALITIES AND ELECTRICAL ENGINEERING.

Notwithstanding the uncertainty which continues to obscure the precise character of the future relations between local authorities and the "undertakers" of electric lighting, there has never been a period when so much active interest has been displayed in the subject by the local authorities. During the last six or eight months our columns have recorded the proceedings of some twenty-four or twenty-five town councils, local boards, or vestries in which the matter has been under discussion. In almost every case the proposals have met with a reception of a more or less favourable character, and at the present moment there are at least ten or a dozen places where a practical outcome may more or less confidently be anticipated. At the same time, it is impossible to read the reports of the discussions in these assemblages without becoming painfully aware of the exceedingly dim and hazy character of the ideas of electric lighting which are still entertained by the average vestryman or town-councillor. Not many years ago we had the pleasure of meeting a gentleman, whose name we have since recognised as that of an ardent champion of local electric lighting, and who held, and still holds, an honoured position in the councils of the local senate in a certain cathedral city. This gentleman assured us that to him personally belonged the honour of introducing the electric light into the West of England, but that "until he bought one and brought it home and tried it for himself" he never did or could believe in the possibility of electric lighting. Our curiosity having been thus aroused, we were invited to inspect the arrangements at his place of business. We went there, and were shown—an electric gas-lighter!

But this was years ago; and since then our friend has doubtless learnt a good deal more about electric lighting, as, indeed, it is to be hoped we all have. There is, however, one

Digitized by Google

point at least upon which the municipal mind still remains in a singularly unenlightened condition. That is as regards the difference between incandescent and arc lighting. We should be glad if it were more widely understood that a vast difference exists from a technical point of view between carrying out a programme of street lighting by arcs, and that of a complete system of incandescent lighting for the interior of buildings. An installation of arc lights is a simple straightforward practical piece of work, into which no element of uncertainty can enter, and complete success ought always to be positively assured; and we may add that from an electrical engineering point of view when accomplished there is absolutely nothing in it to boast about, and very little of technical interest. More than one well-known firm in this country have successfully carried out the lighting of Exhibitions in this and other lands—often at very short notice—upon a scale which would amply suffice for the lighting of the principal streets of a town of 50,000 to 100,000 inhabitants. The only point which requires special consideration on the part of the local authorities is that of the wiring. In Taunton and Waterford, where installations of this character exist, the lamps are mounted upon tall poles, and the wires are carried from one to the other without so far entailing either difficulty, inconvenience, or unsightliness. Where it is necessary to cross the street the wire may either be taken up to the level of the house roofs or, if preferred, may pass underground. We feel sure that, if it were once fully realised how simple and satisfactory a job can be made of arc lighting, its employment would be rapidly extended throughout a very large number of our provincial towns. And in order that this may be fully apprehended it is necessary to insist upon the fact that the question stands upon a wholly different footing from that of incandescent lighting, which has difficulties of its own to contend with, as well as merits of its own to recommend it.

Two objections to the arc light still linger in the public mind. The first arises from the blinking and flickering which it is perfectly true still characterises many public or semi-public installations. But it is a great mistake to suppose that blinking and flickering are inseparable characteristics of the arc light. These effects are nearly always due either to the continued use of obsolete types of lamp, or else to a mistaken economy in the burning of inferior qualities of carbon. There are several lamps in the market which, when provided with good carbons, will burn with a steadiness certainly exceeding that of the gas flame, and which may fairly be compared with that of the incandescent lamp itself. Carbons of the cheap and nasty type will ruin the reputation of any arc lamp. The second objection which is sometimes raised to the arc is that the light is not sufficiently diffused. The usual remedy consists in enclosing the lamp in an opaline or ground glass globe; but this is not altogether satisfactory, as it considerably diminishes the total amount of illumination, and does not always give the needful diffusion. We think it a pity that greater use is not made of the very ingenious and highly successful system of distributing the light over a wide area which is well known to electrical engineers under the name of the "dioptric lens." With the aid of this, or possibly of some equivalent appliance, a very pleasing and uniform illumination may be secured.

There is another branch of electrical engineering which will force itself more and more upon the attention of our municipal authorities, and especially those who are interested in local systems of tram lines. It is one, moreover, which admirably lends itself to employment in conjunction with the lighting of the streets; we refer, of course, to electric traction. Whether this be carried out by the supply of current direct from the machines or by the use of secondary batteries, a great saving may be effected in either case by the combination. To a considerable extent the same plant and same engine-room staff may be made available for both services, and the economy thus effected in the lighting account would go far to balance the increase of cost compared with gas lighting; in fact, we fully anticipate that, under circumstances of an even moderately favourable character, the saving would be more than sufficient to turn the scale in favour of the electric light. We shall not at present go into any details upon the subject of electric traction from the municipal point of view; but for the information of those interested we may state that it is now an ascertained fact that the cost of electrical traction does not, under average conditions, exceed 4d. per car mile, while we have good reasons to believe that in many cases it may even fall below 3d. per mile. For horse traction, on the other hand, 6d. per car mile may be taken as a low figure. These figures include interest and depreciation on the capital outlay in each case. Facts, such as these, if brought home to the municipal mind by practical demonstration, will go far to remove any remaining doubts as to the economical uses of electricity in many of our most populous towns.

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

On Wednesday last the further hearing of this action was proceeded with before Mr. Justice Kay.

The ATTORNEY-GENERAL proceeded with the re-examination of Mr. SWAN. Witness said he could not say when he first began experimenting with heating the lamp before sealing. He patented the method in the beginning of 1880, and he thought it had been used for a considerable length of time in his lamp before patenting. He did not know at the time that the same process had been described by Mr. Edison, nor did he know of it now. Asked whether he knew of any publication of carbons of wood splints for incandescent electric-light lamps before Edison's patent of 1879, witness said he thought King's specification might be construed to embrace wood splints. In the various patents he had taken out his object had, of course, been to secure some monopoly in the lamps. He used platinum caps all through 1879, and to that extent he had departed from the elements of F J B 1. There had been a good deal of trouble experienced when the platinum wire was simply taken through the glass, arising from the cracking of the glass where the wire was sealed in. That defect was one which could be explained now. These caps were adopted as a means of preventing this accident, and they did prevent the cracking.

Mr. CHARLES HENRY STEARN, in reply to the ATTORNEY-GENERAL, said he was managing director of the Swan United Company's foreign business. In 1877 he was residing at Rock Ferry, near Birkenhead, and he was then a clerk in the Bank of England. He had experimented with the Sprengel pump since 1872. From the end of 1877, during part of 1878, and through 1879 and 1880, he was engaged with Mr. Swan in experimenting. He first had some discussion or correspondence with Mr. Swan on the matter in August, 1877, and from that time down to the end of the year 1879 he at intervals had received carbon from Mr. Swan. Fred Topham used to blow the bulbs, and no one besides him had blown the bulbs before the fire, which occurred at the end of 1879. It was suggested by Mr. Swan that they might obtain elasticity in the carbon. In the first case it would be seen that the strip of carbon was rigidly fixed at the ends, whereas in this case each piece of carbon was free to move a little. That gave room for expanding and contracting without breaking, and it afforded an easier method of mounting for the glass blower. In the first case the carbon was a very thin fragile piece of carbon, and the glass blower, while fusing the wires at either end, was very apt to break them, because, while he was fusing one the other was hanging loose. Of course, with the skill attained at the present day, there would be no difficulty whatever.

Witness was then referred to his letter of the 24th June, 1878, in which he spoke of the carbon filaments being too fragile for commercial purposes. Witness explained that his impression was that if these filaments were sold on a large scale, they were so delicate that they would be inevitably broken in carriage. That was his opinion for a long time, until, in fact, the filaments had been strengthened by the Cheesborough process. From an account which he delivered to Mr. Swan of his out-of-pocket expenses in this matter, it appeared that he paid the glass blower from 2s. to 3s. per lamp. Among the lamps charged for in that account were four large experimental lamps, one of which contained a piece of asbestos, which was used for the purpose of insulating the coils—it was placed between two convolutions of the wire—a coil inside and outside. He did not use carbonised thread up to the 12th January, 1880. The lamps they

Digitized by Google

were making had platinum caps. The use of copper necessitated the use of platinum caps, because they could not seal the copper to the glass. Referred to his letter of the 29th July, in which he suggested that the pencil should be put on blocks, by which means the only apparent source of danger would be removed, witness said the carbon pencil was let into two larger cylindrical blocks at the end. They were of larger diameter, for the purpose of reducing the temperature of the carbon at the point of contact. The carbon pencil had been let into the blocks by drilling. The effect of heating and cooling was to cause it gradually to rupture the contact. Before writing that letter he had not tried the thinning of the carbon in the middle. In his letter of 3rd October, 1879, he had referred to Mr. Edison's experiments in the use of platinum wire in vacuo. There were two points in connection with those experiments to which he wished to draw Mr. Swan's attention. The first was that Edison was expelling occluded gas from the platinum; the other was that he was using a vacuum for his lamp, as distinguished from nitrogen or open air. At that time it was understood that Mr. Swan should take out a patent when they had thoroughly investigated the ground. He did not at any time before then know the details of Edison's proposals. Referred to his letter of the 19th November, 1879, in which he proposed to try the lamps with the Birkenhead Corporation's engine, witness said that prior to that date he had only tried them with batteries. He had not used carbon threads or carbonised cotton before May, 1880. It was not true that in 1879 he had alight in his house thread lamps made out of blocks of fibre of hemp twisted. They had no loop lamps before the year 1880; certainly not until quite the end of 1879. The circular lamp may have been made in December, 1879, although exhibited in 1880. Through the year 1879 they were using platinum caps. In March, 1880, he took another house for the purpose of a laboratory to enable him to conduct the experiments on a larger scale. Before then he had not had any dynamo. The Cheesborough process was first used in December, 1880.

Did you know Cheesborough at the time?—No.

Had you thought it out for yourself?—I think the origin of it was that some time before—I do not know how long—I had sent a thread lamp to Mr. Swan, and Mr. Swan reported to me that it was entirely different from any that he had had before, that its resistance was lower, and that it had a bright silvery appearance. He asked how it was done. I never knew how it was done; it was accidentally obtained.

Cross-examined by Mr. FINLAY: He had written a Paper for publication in the *Electrotechnische Rundschau*; and in January, 1885, a Paper was published in that magazine in German, with his name affixed to it. The Paper was never sent to him for correction, and he was not at all responsible for it. The original article was much longer; he could not read the German, but he could not accept the English translation from the German (which was in court) as his article. The original manuscript had been returned to him, but some portions of it were now missing. Witness was then cross-examined upon several passages in the article. Asked in reference to one passage, was there any essential principle of incandescent lighting which was not known before November, 1879, witness said it all depended upon what the "essential principles" were defined to be. Of course, essential principals and the carrying of them into effect were two different things.

Is it not the case that all that remained to be done in November, 1879, was the perfecting of the details and the carrying of those principles into practice?—I should say so.

Witness, continuing, did not think the necessity for or desirability of a thin carbon conductor for an electric lamp was generally recognised in 1877; or, rather, the necessity for it had been, but not the method of production.

The necessity was well known to everyone of making the carbon conductor as thin as possible?—Yes.

Witness was then examined upon the statement in the article that during the years 1878 and 1879 he had used "other kinds" of carbon. Witness referred to the original manuscript and found that he had used the phrase "other kinds," but explained that that was a careless expression. What he meant was, "other forms," such as those shown in the various drawings that had been put in—paper carbons and round Carré carbons.

Witness here explained that an illustration of Lane-Fox's lamp had been put in by the editor, but the editor had acknowledged that he had used the illustration of a lamp of a later date than that referred to in the article. That was a very material alteration, as it would suggest that Lane-Fox had used a filament as early as 1878.

Witness was then examined upon this passage: "It appears that this lamp (Edison's patent of November, 1879) had no practical success; it was never reduced to practice." On referring to the original manuscript he found that the words he had used were "no practical success appears to have attended this early lamp." That of course was to a considerable extent a matter of opinion and information, but he was not aware of lamps made according to the details described in the patent having been used commercially.

Do you think it likely?—That, of course, is a matter of conjecture. I have not seen them nor heard of them being sold. I can say no more.

Besides attending to the management of your own company you pay some attention to what has been going on in the electrical world?—I must say for some time past I have been unable to do so; so much litigation has been going on in both countries that it takes up all one's time.

When you wrote that passage had you not reason to believe it was true that it had never been successfully made or sold?—I said it was not in commercial use.

Apart from subsequent improvements, did you ever know of any lamp being made under this patent?—I think it has commonly been made. I was confining myself entirely to the commercial use.

Mr. JUSTICE KAY: Do you know of any lamp?—I believe several lamps have been put in in the course of this trial.

Mr. FINLAY: Did you ever hear of any lamp being made under this patent until Mr. Gimingham made it for the purposes of investigation?—I think I heard previously that lamps made according to the particular description in the body of this patent had been brought over from America, but I had never seen them.

Were the lamps brought from America, bamboo lamps?—I was told not. I was told lamps with a carbon filament had been brought from America.

Witness was then examined upon another part of the article, in which he was made to say that to Edison must be assigned one of the chief and most important positions in the band of inventors, but that his scientific results did not precede in any manner, either in invention or merit, those of other eminent inventors. Witness said that he had not the original manuscript of that portion of the Paper, but probably that was substantially what he had written. The words, "in any manner," were perhaps going a little too far, and he hardly thought that they represented what he actually wrote.

Did you say in substance that Edison had not been before other inventors in this matter of the incandescent lamp?—Most probably I did, or something to that effect, in regard to the general principles of the incandescent lamp.

General principles, I understand you to say, Edison did not anticipate?—It certainly was my opinion that he did not.

And that is your opinion now?—Yes; that is my personal opinion, for what it is worth.

Did not Edison anticipate any of the details?—There are a good many details in that patent, and I could not answer you offhand.

Having read the patent when you wrote that paper, did you not regard that patent as unimportant?—Yes; but you must remember I am dealing with the German patent. I am not dealing with the English patent.

In reply to further questions witness said that Mr. Turner was in the habit of coming to his house in 1879. He could not swear that he did not show some incandescent lamps to Mr. Turner in the summer of that year, but he could not remember doing so; certainly Mr. Turner did not then see the carbon conductor in a horseshoe form. He remembered Mr. Allon being employed to fit up batteries for him. He could not fix the date exactly, but he thought it was later than the summer of 1879. He had no doubt that Mr. Allon had been introduced to him in 1878 or 1879 by Mr. Turner. He was not, however, prepared to contradict Mr. Allon if that gentleman stated he had been at the house in August, 1879, and seen incandescent lamps.

Will you swear that he did not see the carbon conductor in August, 1879?—I have a general recollection that we did not use the arched forms until we had the hair pins.

Did you hear Mr. Swan say that he ordered the hair pins in the spring of 1879?—Ordering them and getting them are two different things. Mr. Swan gave the order to Carré; secondly, as those are unusual things to make, it would be some time before Mr. Swan would receive them; a still further time would elapse before Mr. Swan had time to attach them to conductors and send them to me, and a further time would elapse before I did anything with them.

When do you say these hairpin conductors were first mounted? I can only answer that by reference to the letters. On the 26th of November I find they are mentioned. My recollection, confirmed by the correspondence, is that we did not use them before that date, or only a few days before.

The Court then adjourned for luncheon.

On resuming Mr. STEARN was asked whether Mr. Swan during 1879 was reducing the size of the carbon as much as possible. Witness said his first interview with Mr. Swan turned entirely on the question of the size of the carbon conductor.

You and he thoroughly understood that the great *desideratum* was to get the conductor very much thinner?—As thin as possible.

The question of a thin carbon was the first before you?—A thin conductor if a high electromotive force was got.

That was in October, 1877?—Yes.

You use the term filament to denote extreme thinness?—Yes.

Did you not show Mr. Turner and Mr. Hannen, in 1879, lamps with carbon conductors of extreme thinness?—I have no recollection of showing them anything, but at that time I did use such lamps.

Have you any doubt they saw them?—Probably I had them there.

Would not thread light be a correct description of the lamps you were trying in 1879?—It would be a correct description.

Did you make conductors of the arched form in 1879?—I should say not.

Are you prepared to say, upon your oath, that in the summer of 1879 you had not lamps with the conductor of an arched form?—My belief is not, but I cannot swear to it.

The provisional specification taken out in January, 1880, by Mr. Swan for the use of paper—had you not, during the year 1879, been trying lamps made by Mr. Swan somewhat in the fashion indicated?—I had not tried any lamps made by Mr. Swan.

I mean the form. Now, I ask you whether you had not, during 1879, been trying conductors made in the form therein described—horseshoe form?—No, I do not think we had.

When did you first try the horseshoe form?—In December, 1879, or the beginning of the following January. I remember exhibiting it in January.

Paper you had been using from 1877 onwards?—Certainly.

Re-examined by the ATTORNEY-GENERAL, witness gave details of his applications in various letters and from his diary to Mr. Swan for carbons for experiments. He had a distinct recollection of being annoyed at being kept waiting for carbons.

Have you any connection with the plaintiff company at all?—Only as a shareholder in the Swan Company.

In the German Paper were you advocating Swan?—I was endeavouring

Digitized by Google

to overthrow Edison (laughter). I was endeavouring to educate opinion in Germany.

What did you mean when you spoke of "extremely thin?"—An extremely small cross-section. If it is a thread it will be a circular section; if it is not it will be a rectangular section.

CHARLES FREDERICK TOPHAM, examined by Mr. BREMNER, said that he assisted Mr. Stearn in his laboratory work. Witness was given paper carbons, which he mounted in tubes for Mr. Stearn. Cases of breakage occurred in the mounting. He was next occupied with putting carbon pencils in bulbs. He thought about six were given him.

Mr. JUSTICE KAY several times complained that the replies were inaudible.

Witness said that he remembered the various removals of Mr. Stearn's laboratory. Before it was moved downstairs the shape of the conductors given to him was straight. No other shape was used in the upstairs laboratory. After the removal of the laboratory downstairs the next change witness remembered was to carbon rings made of paper. Witness remembered a fire at Mr. Stearn's, and it was about that time that the rings were adopted. He remembered having thread filaments given to him to mount, and that was after a removal to another house. He mounted no thread filaments at the old house.

Do you remember any change in the nature of the carbon paper after the fire?—No.

Except from the places you were working at have you any recollection of the dates?—None whatever.

About how many lamps do you believe you delivered to Mr. Stearn before the removal downstairs?—About eleven or twelve.

And after the laboratory was shifted until you went into the new house?—I could not say.

Mr. Roberts used to come to Mr. Stearn's house occasionally?—He did.

Cross-examined by Mr. FINLAY: He would be about 15 years of age at the time, and he had no recollection of the various dates.

When did you have your memory refreshed about all these things that occurred so many years ago?—About a week or a fortnight ago.

And you recollect them all?—Yes.

Which happened in 1879?—Yes.

Have you got any notes?—No. He knew the carbon rings were made of paper from being told by Mr. Stearn. His eye would not have told him that.

Can you fix the time of being given the hairpin conductors?—About the time of the fire. Certainly not before the time of the fire.

You were spoken to a week ago about this; how do you profess to recollect the things so precisely?—I have thought over it since. I have made drawings. I made drawings about three weeks ago, and others about eighteen months ago.

Were the latter for the Woodhouse and Rawson trial?—I do not know. Those are the only drawings I have made.

Witness, continuing, said he had been engaged during a number of years blowing lamps, and he might say 100,000 had passed under him.

Now, have you got anything whatever to enable you to fix the different kinds of conductors?—Only the numbers that were exhausted in the different rooms.

Re-examined by Mr. ASTON, witness said he took an interest in the work, and he had no doubt about what he had mentioned so taking place. He blew the bulbs himself, and was in the habit of taking them to Mr. Stearn himself, and his memory was distinct.

Mr. JOHN IMRAY re-called, examined by Mr. MOULTON, was the next witness.

You have had experience as a manufacturing engineer?—From 1850 to 1867.

You have heard the evidence as to using charcoal powder during carbonising; was that common ordinary knowledge in 1879?—I am sure it was, long before.

Can you give an example of the use of charcoal powder for the purpose of preventing oxidation?—In tempering fine steel works such as the hair-springs of watches. That is a common thing. I succeeded to the business of the Patent Axletree Company, and we had to caseharden the axles.

Mr. JUSTICE KAY, upon witness's going into details of the process, intimated to Mr. Moulton that he did not think it would throw any light on the case.

Witness, continuing, said that he had made an experiment, taking two crucibles, each of a capacity of 200 cubic centimetres. He put into each of them chips of wood, small strips of paper, pieces of thread and vegetable fibre—Mexican fibre. Having put the articles loosely into the crucibles, he poured sand upon them so high as to nearly fill the crucibles. One of the crucibles he left dry, and in one he poured water, so as thoroughly to soak the sand. The lids were then secured, a hole being made so as to allow gases and steam to escape. He then heated the crucibles to a sharp heat, and then examined the contents. He should mention that before putting the contents in the crucibles he tried to get electricity through them, but could not get a spark. Afterwards he found them fair conductors, and could send electricity through any of them. The product of the carbonisation of the wetted one took a current up to 30 volts.

With regard to sand for the purpose of carbonisation, was that common knowledge before 1879?—Yes. In the very first number of the *Mechanic's Magazine* for the year 1823 there is a passage describing the preparation of charcoal for drawing, which employed it. On the 28th of May he saw carbonisation done at the plaintiff Company's works. In the first place he saw a boy making filaments from a putty of lampblack and tar, rolling them between two pieces of glass. That was done rapidly. They were then cut into short lengths, and short pieces of platinum were attached to the ends. He saw strips of bamboo with platinum attached, in the same way pieces of thread, and thread with the putty. A number of these were put into a small iron box, laid loosely, and subjected to gas heat, and upon being opened all were found to be well carbonised. All were quite fit for electric lamps. He found, upon testing, a thread smeared with lampblack fitted with platinum wires gave a resistance of a million ohms. He then tried heating it with a spirit lamp, but it never got to red heat.

Mr. JUSTICE KAY: None of these experiments were at a heat equal to a coke furnace?

Witness: No. He took it out and found it to be partially carbonised, giving a resistance of 38,000 ohms. After being replaced and subjected to a sharp white heat for twenty minutes it became thoroughly carbonised, with a resistance of 175 ohms, and it was mounted in a lamp. The gas muffle was the ordinary furnace for laboratory purposes, and gave what was called a sharp red heat. Witness saw other lamps made, filaments of the putty run out and coiled upon a helix of copper wire. He was shown a number of lamps burning—twenty-five—of which four were helically coiled. They all burned well during some four hours. The effect of the helix seemed to him to be the best lamp of all. That was a matter of taste, but it was a sort of central star. It had a pleasing effect upon the eye.

From what you saw at the works, what conclusions did you draw as to the mode of manufacture given in Edison's specification?—I saw no practical difficulty about it; a little care in manipulation—that is all.

Do you think there is any direction in Edison's specification which is not the result of actual trial?—I am satisfied that everything that is described by Edison is the result of practical trial by himself. With respect to filaments in which the tar had not been sufficiently extracted, samples of which were submitted to the Court, witness did not think the presence of an attenuated vapour in it would affect the light seriously; but it was a question of degree.

At this point His LORDSHIP said the Court would adjourn until the next day rather than commence a new point.

THURSDAY, MAY 31ST.

EXPERIMENTS TO BE MADE IN EDISON'S SPECIFICATIONS.

On the Court re-assembling on Thursday, His LORDSHIP suggested to Mr. Moulton that it would be useless taking the opinions of many scientific witnesses, there being so many facts before the Court, and he should, so far as he was concerned, decide upon facts.

Mr. MOULTON replied that he would compress the evidence as much as possible.

The cross-examination of Mr. IMRAY by Mr. FINLAY was then proceeded with.

Mr. JUSTICE KAY intimated that he was satisfied that there had been previously no trade in which carbonising things so fine as filaments was carried on.

Mr. FINLAY said he would not go into that point then. To the witness: With regard to sand, what kind did you use?—Ordinary sand, such as chemists use in sand baths—silicious sand, of no particular selection. The crucibles he had referred to would be about 13 cubic inches—3 inches high, 2 inches at the mouth, and 1½ inch at the base. He did not know that that was much smaller than those used in the manufacture of filaments commercially.

Would there not be oxygen between the interstices of the sand?—Yes.

Would not one-third of the cubic contents of the crucible be air?—Possibly; it would depend upon the fineness of the sand.

Would not the carbon filaments under such circumstances be consumed?—The oxygen would not get to the filaments.

Mr. MOULTON here mentioned that the crucible referred to was just twice the size of the one used by Mr. Crookes.

Mr. FINLAY (to the witness): Would not the oxygen get intermingled with the gases given off in the process of carbonisation?—In the course of time. The experiments, witness said, took from half-an-hour to an hour, but he was unaware of the time occupied in the commercial process. In nine or ten hours there probably would be combustion in a large crucible.

How was it that in your experiments the gases were not consumed?—I do not know, except that they were not.

Can you suggest any explanation of the phenomenon?—The quantities of gases given off were sufficient to neutralise the oxygen.

Mr. JUSTICE KAY asked why keeping it at a white heat for eleven hours would have the other effect?—Witness explained that in that time there would be sufficient diffusion of gases to enable oxygen to get in the box from the outside.

Mr. FINLAY: Packing is not required?—I do not think it is at all necessary.

Mr. JUSTICE KAY asked the witness his views as to the nine or eleven hours' process, which had been mentioned as being far too long?—Witness expressed his inexperience of that length of time in that process, and Mr. Justice Kay said he would mark the question as not answered.

Mr. FINLAY (to witness): Do you seriously suggest that these filaments could give off gases to the extent of more than 1,500 times their own volume?—No; I say they drive enough oxygen out to prevent combustion.

You were a witness in the Woodhouse and Rawson trial; did you hear evidence given there that the carbon in lamp F J B 1 had been carbonised before being introduced in the form of a pencil?

The ATTORNEY-GENERAL, interposing, said there had not been evidence to that effect.

Mr. FINLAY, in support of his question, then read extracts from the evidence given in the Woodhouse and Rawson trial. From Sir Frederick Bramwell's evidence: "I have no doubt it has been worked down from a thicker piece of carbon. It would be a lamp of low resistance;" and from Dr. Hopkinson's evidence as to conductors being carbonised before being put into their final shape.

After an intimation from the ATTORNEY-GENERAL that the passages

Digitized by Google

required to be read in their connection with others, the point was not further pressed.

Re-examined by Mr. MOULTON: In your experiments were any unusual precautions taken to prevent the destruction of the fibre?—No; the experiments could be easily repeated.

With regard to the process of carbonisation used now in manufacturing, have you any experience?—No.

Mr. JUSTICE KAY: Do you know enough of the commercial manufacture of filaments to be able to tell me whether they are carbonised in gas mufflers or not?—No.

Did you take any note during the carbonisation?—Yes; I have the book. The box and filaments were put in the muffle at 12:20, the heat being then on, although not fully; it remained ten minutes at a moderate heat, and was then put full on. The box was taken out at 1:20, left to cool, and opened at 2:5.

Can you explain why your experiments succeeded and some of Mr. Crookes's did not?—No, unless he kept them a very long time heated.

Mr. CHARLES HENRY GIMINGHAM was the next witness examined by Mr. MOULTON. He was, he said, the superintendent of the manufacturing department of the plaintiff company, and had been in their employ some seven years. In the course of the manufacture witness said that when gas was used, it was an ordinary furnace, but coke was afterwards returned to. So far as he knew the heat would be just about the same as that used by Mr. Imray when gas was used. A long period for carbonisation had been found to give inferior results. With regard to packing, a mixture of lampblack and charcoal powder was used about seven years ago, but since then a good deal of plumbago powder had been used.

What was the heat when the gas muffle was used?—It would easily melt brass, but would not melt cast iron. It would melt copper. I have carbonised a great number of filaments in the manner described by Mr. Imray.

You have also carbonised with charcoal packing?—Yes.

Will you tell his lordship if, in your opinion, all the ways referred to in Edison's specifications will yield practical results?

Mr. JUSTICE KAY: I will not take opinions. If you will give me what has been done I will take it.

A list of the lamps in the boxes in court was then handed to his lordship, and lamp No. 51, described as "tar putty spiral," put in.

Will you tell his lordship what, in your opinion, are the advantages of the spiral lamps?—The spiral lights, in my opinion, give a more pleasant light than the single loop lamps. The pleasantness comes from a more uniform light, and the eye not being liable to distinguish the hairpin shape of the carbon.

Mr. JUSTICE KAY: I do not know what Mr. Finlay thinks, but I think it would be more satisfactory if experiments were tried before experts on behalf of both sides.

The ATTORNEY-GENERAL: I have no objection.

Mr. JUSTICE KAY: I should like all that is suggested in Edison's patent made in that way, and whatever is made tried.

Mr. FINLAY: I think that would be more satisfactory.

The ATTORNEY-GENERAL: These lamps (now in court) should be tried, too. There is one guarding observation I would make—that I do not at all agree with my learned friend that the fact of the defendants' working improvements has the slightest bearing on the question of the validity of this claim.

Mr. JUSTICE KAY: I am only speaking on the evidence. It will be a great deal more satisfactory to me if the manufacture is carried out in the presence of both sides. Seeing that there is now a serious conflict of evidence I should like to have the results tried.

The ATTORNEY-GENERAL: It shall be done in the presence of anybody named by your lordship.

Mr. FINLAY: What the Attorney-General suggested, to test the lamps already made, would hardly meet the case.

Mr. JUSTICE KAY: Certainly. Now, if you can get some eminent experimental witnesses to make a joint report——

Mr. FINLAY: How long would it take?

Mr. JUSTICE KAY: Before Monday, surely.

The ATTORNEY-GENERAL again suggested the testing of the lamps already made.

Mr. FINLAY: That is no use.

The ATTORNEY-GENERAL: His lordship will say.

Mr. JUSTICE KAY: I am in face of a very direct conflict of evidence.

The ATTORNEY-GENERAL: It is your lordship's wish an independent person shall be there as well—Sir William Thomson.

Sir Horace Davey now entered the court, and, addressing the learned counsel,

Mr. JUSTICE KAY said: I should like it conducted in this way; six or more lamps made, and the whole manufacture from the beginning—enclosing the carbon in the lamp, exhausting it, and so on—should be carried out according to Edison's description in his specifications, and I want witnesses to see that it is fairly done, a "moderator" I may call him, who will give me his independent report. Do you see any objection?

Sir HORACE DAVEY: It seems to be an advantageous course to take.

Mr. JUSTICE KAY: I should think two expert witnesses.

Mr. FINLAY: Of course, if the lamps are to be run for duration.

Mr. JUSTICE KAY: They will have long enough if they run until the case ends (laughter).

The ATTORNEY-GENERAL: The question of duration I think my friends will find will not avail them.

Mr. JUSTICE KAY: Run them until they break.

Sir HORACE DAVEY: The selection of the "moderator"?

Mr. JUSTICE KAY: I thought you would relieve me from that.

The ATTORNEY-GENERAL mentioned Sir Henry Roscoe's name.

Mr. FINLAY: Is there to be packing?

Mr. JUSTICE KAY: You may do it both ways. It would be most satisfactory to me.

The ATTORNEY-GENERAL: Three ways—sand, charcoal, and without.

Eight or nine cases, containing about 300 lamps, were then put in, manufactured by the plaintiff company, considerable time being occupied in their manufacture being formally proved by Mr. Gimingham, and their being given into the charge of the officials of the court.

Sir HORACE DAVEY: I understand, my lord, that a case containing 150 exhibits has been put in *en bloc*. How it is possible to cross-examine upon that I cannot conceive.

Mr. JUSTICE KAY: Upon this part of the case, as to what is practicable under Edison's specification, I shall pay more attention to what is done by the gentlemen who are going to meet and experiment.

The cross-examination of Mr. Gimingham by Mr. BREMNER was then proceeded with.

You never made any filaments for sale without using plumbago?—Without using packing, I think not, at no time in my experience.

You tried lamps for duration at 10 watts per candle-power?—That was an excellent efficiency in 1879.

What is the efficiency to-day?—3½ to 4 watts.

With an ordinary sixteen candle lamp have you tried how much one made by you will give out at 10 watts per candle-power?—I have not tried; probably not more than 8 candle-power.

Would it not be nearer four or five? Are you in a position to contradict that?—No.

What is E G 59? (the lamp being taken from one of the cases put in).—20 per cent. of oxide of zinc wound between a copper helix. My brother made it.

You would not call him an ordinary working man?—Yes, I should.

Do you suggest it is a close spiral such as is shown in Edison's drawing?—I do.

Sir HORACE DAVEY: Perhaps your lordship will look at it?

Mr. JUSTICE KAY, to witness. Is it as close as is shown in Edison's drawing?—I think so, my lord.

Mr. BREMNER was proceeding to question witness as to its being what Edison meant by "coil," when

Mr. JUSTICE KAY said that that must be left to him.

Mr. BREMNER (taking another of the lamps put in to witness): E G 62, what is that?—20 per cent. oxide of zinc coated with silicon.

Did you make it with your own hand?—I did not.

Did your brother coat it with silicon?—Yes, I saw him.

What silicate did he use?—Not silicate at all; pure silica.

What part of Mr. Edison's specification did you consider that was carrying out?—When he tells you to use a "non-fusible, non-conducting substance," I believe his words are.

Take J 18, put in as a lamp made in sand. Do you call that a good commercial lamp?—It is an amateur's lamp (laughter).

Replying to his lordship, witness said that the furnace was at times kept going for 13 to 14 hours, because that gave more carbon from each thread. It was raised to a white heat at the end. It brought the carbon to its final resistance.

I want to know the advantage of keeping it for two hours at a white heat?—To facilitate the measurements in order to make lamps of the various kinds required. The carbon being brought to its final state, the measurement of its diameter can be taken, and its resistance taken, and it can be brought to the E.M.F. and candle-power required.

Then this raising of the heat conduces to the duration of the carbon when used?—No; it does not.

I understand you always do it now?—Yes.

And is the sole advantage the one you have described?—It is a very important advantage.

It comes to this, that you are more easily able to measure?—The resistances are more uniform, and we can make our calculations with more certainty, owing to that. It makes them denser, harder, and better to handle.

Mr. EDWARD GIMINGHAM confirmed the last witness's evidence.

Mr. R. T. GLAZEBROOK, examined by Mr. MOULTON, said he had made various experiments with Bunsen batteries and carbons of various sizes.

Cross-examined by Sir HORACE DAVEY: The result of one experiment, tried with a carbon one millimetre in diameter and twelve in length, was that it swelled suddenly to three times its size, and fused.

Then, the result of what Deprez did producing a carbon, which was denser, harder, brighter, and tolerably solid—my lord will say whether it was the result, or not—you cannot have pursued the same process?—I did not succeed in so doing. Witness said that he had referred to Blavier's works, and the experiments were conducted before electrical measurements had attained their present accuracy.

Re-examined by Mr. MOULTON: Blavier took his measurements before ohms were invented, and his method was not correct.

This concluded the witnesses for the plaintiffs, and

Mr. JUSTICE KAY said that he should like notes to be taken during the experimental manufacture.

Sir HORACE DAVEY said that Prof. Crookes and Prof. Silvanus Thompson were selected as experts by his side.

Mr. ASTON said that, in the absence of the Attorney-General, he could not mention the names for his clients, but he would settle with his learned friends on the other side.

After some discussion as to when it would be convenient to resume the hearing of the case,

Mr. JUSTICE KAY said that it had better be mentioned in court to him to-day (Friday), when the arrangements for the experiments were completed.

REVIEWS.

A Key to the Mysteries of Water, Electricity and Heat. By WILLIAM BOGGETT. (London: Trübner and Co.)

Mr. William Boggett, the author of this treatise, is the fortunate possessor (as he assures us on page 1) of a copy of Chambers' "Encyclopædia," and in the article on "Water" he finds the following passage:—"It is now known that water is a compound of oxygen and hydrogen, in the proportion of one equivalent of each." In the true spirit of scientific caution, Mr. Boggett observes that "unless this statement was in accord with the admitted belief of scientists it is very improbable that the writer would have assumed it to be a fact;" and Mr. Boggett "therefore feels justified in so regarding it." We are glad to be in a position to assure Mr. Boggett that his conclusion as to the belief of scientists is fully justified. But Mr. Boggett himself does not share this belief; he recalls the fact that water is a fluid, and "conceding, for the sake of the argument," that oxygen and hydrogen are its only constituents, he proceeds to inquire "from which of them, or both, does its fluidity proceed?" They are, he says, "simply two dry gases, and could no more produce a fluid than they could produce gold." This is a bold assertion, but possibly not too bold on the part of one who possesses a key to the mysteries of water, electricity and heat. We might stay to remark here that, according to accepted definitions, oxygen and hydrogen and other dry gases are themselves fluids, although not liquid at ordinary pressures and temperatures; but this might savour too much of impertinent quibbling, and it is better to learn from Mr. Boggett what is the true constitution of water.

We gather, then, that water consists of "oxygen, hydrogen, electricity and heat," in proof whereof Mr. Boggett adduces the well-known endiometer experiment, in which it is palpable to everyone that the oxygen and hydrogen do not unite to form water until electricity and heat are added. Only one consideration hinders us from at once accepting this argument as a triumphant vindication of Mr. Boggett's position. But Mr. Boggett has himself taught us to inquire from whence does the fluidity (or, as we should prefer to say, the liquidity) proceed. On this point we are still left entirely in the dark. If we could only feel convinced that either heat or electricity, or both, were liquids, or even semi-liquid, we think we should almost be prepared to endorse Mr. Boggett's views. Meanwhile, we cannot but feel that for us electricity is a mystery still.

Geneva.—The inhabitants of Geneva are at last awake to the fact that the Rhone as it leaves the lake affords an admirable source of natural power. Three large turbines are already at work, by means of which a high-pressure hydraulic system has been effected. One of the first uses it is intended to make of the several thousand horse-power which will be available when the works are complete is to drive the dynamos at a large central station. The Conseil Administratif are already considering the plan of their president, M. Turettini, for lighting the town theatre, which is about 700 yards from the central station. It is proposed to instal 2,400 lamps in place of the present gas-burners, and at the theatre itself to have a dynamo and accumulators capable of running an additional 100 lamps in case of emergency. The mains are to have a cross-section of about 400mm., so as to reduce the loss in transmission to 10 per cent. Low-potential dynamos of 210 or 220 volts are to be used. M. Turettini's estimate amounts to 150,000fr. (£6,000); he allows £576 for the 1,400 yards of main cable, £156 for the laying of the same, £4,800 for the 2,400 lamps, fittings, &c., the balance of £468 being absorbed in etceteras. The annual cost of the installation is about £1,120 for 210 representations per annum.

"The Progressive Age."—The leading American gas lighting journal, which appears under the title of *The Progressive Age*, has removed its offices from Philadelphia to New York, and will appear fortnightly instead of monthly as hitherto. *The Progressive Age* devotes a great deal of attention to electric lighting matters, and will compare favourably with any journal of the same class published on this side of the water.

JUVENILE LECTURES.

THE APPLICATION OF ELECTRICITY TO LIGHTING AND WORKING.*

BY W. H. PREECE, F.R.S.

Lecture II.

(Continued from page 85.)

We will now go back to some of the other purposes, and the one purpose that I wish to refer to is the power that electricity gives us to utilise the waste powers of Nature. Wind, tides, and falling water are to be found everywhere, and if they can be utilised economically will certainly be so used. I have shown you, in the case of the Portrush Railway, how water-power is utilised in this way. In the Bessbrook and Newry Railway water-power is utilised in precisely the same way. At Craigside, near Newcastle-on-Tyne, Lord Armstrong is able, by means of the energy of a waterfall in his grounds, to light up his house and to do various other things. In France M. Felix has used this same property for ploughing.

Again, at the Paris Electrical Exhibition, there was a Siemens lift worked by electricity, by which people were raised from the floor to the gallery; Dr. John Hopkinson has also worked in this direction. This system of lifts (Fig. 12) worked by electricity is utilised at the present moment in London at at least two banks—the River Plate Bank and the Bank of Rio Janeiro—for carrying books and bags between the various floors of the premises. This power of electricity is more easily applicable for lift purposes than almost any other.

There is an experiment which I wanted to show you earlier, and as it is rather a pretty one I will show it you now; it is the power that electricity has to draw or raise a weight. This was used by Marcel Deprez in Paris for an electric hammer. I have here a weight that will pass up through a coil of copper wire. When a current of electricity is sent through the coil the weight is sucked up, and there you see, by means of electricity I am able to produce blows, and it only requires more electricity and a heavier weight to produce the effects of a hammer.

There is another application of electricity that has been attracting a good deal of attention at Brighton. Mr. Volk, who has done a great deal towards the application of electricity down there (he has laid an electric railway along the beach), has started an electric dog cart. He has fitted a dog cart with batteries, and it goes bowling about Brighton without a horse. He, his wife, and daughter, are to be seen taking their airing along the Parade in a vehicle that looks like a dog cart, but there is no horse in it.

When I was last in America, Mr. Edison, who is one of the most ingenious men alive, gave me what he calls his electric pen. It is in the form of a pencil, but instead of lead, the core of the pencil consists of a very fine needle, which has an up and down play of about $\frac{1}{16}$th of an inch, and by its movement backwards and forwards, caused by a little electro-motor, the

* A course of two Lectures delivered before the Society of Arts on January 4th and 11th.

Digitized by Google

point makes small holes in the paper. I write "W. H. P." To take copies of what is written, I should simply rub an ink-pad over the little holes, when I should have "W. H. P." printed on the paper, and could strike off as many copies as I liked.

The motor that Mr. Volk uses for his dog-cart in Brighton is also used for ventilating. I have here a fan, which is moved by an Immisch motor, which rotates at the rate of 500 or 600 revolutions per minute. As I showed you before, this same power of electricity can be used for working sewing machines.

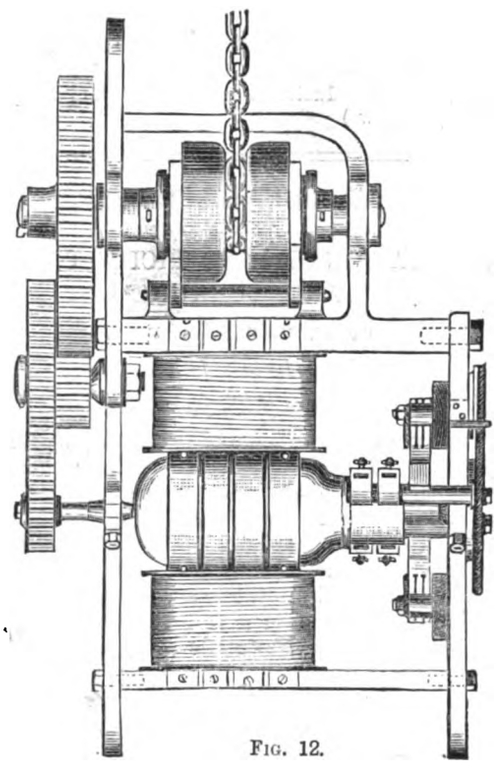

FIG. 12.

This sewing machine is worked by an electro-motor, and it must be a comfort to those who constantly use such machines for domestic purposes, as by the use of electricity much fatigue is prevented.

Electricity has been applied to boot cleaning, to knife

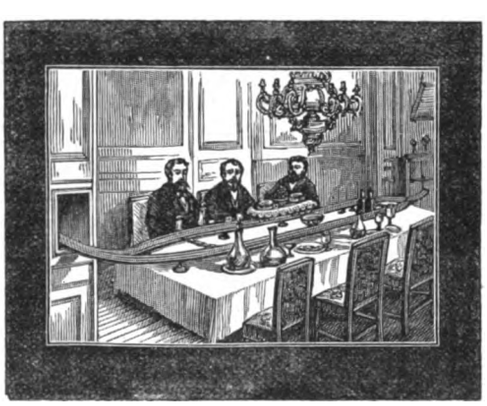

FIG. 13.

cleaning, and there is no reason why it should not be used for churning. It can be used, as you have seen, for ventilating. It can be used for sweeping. The same power can be used for mowing machines, and many other purposes. Sir David Salomons has devoted his whole life to scientific pursuits, and his house is fitted up with electricity. He has a workshop fitted with all the latest and most perfect tools, all of which are worked by electricity. We are going at such a pace in the diminution of labour, that one of these days I should not be at all surprised to see that electricity will work the dirty iron ore from the mines of Bilbao into a magnificent 10in. gun, better than anything that the establishment at Woolwich has produced. For toy purposes we have lots of things on the table, ships, electromotive engines, zoetropes, and all sorts of things worked by electricity, but they are for your merriment after the lecture, rather than for your instruction during the lecture.

A distinguished electrician has dispensed with waiters at the dinner table by the use of electricity (Figs. 13, 14,). He has fitted a small electric railway on the dining table, along which the courses are carried and removed as required, and you now see a picture of the arrangement on the screen.

The clipping of horses can be done by this electric power better than by the hand process, with less injury to the animal, and far better than the old singeing process.

Electricity is also used for propelling boats, and you see a picture of the "Cygnus," a boat used at the Paris Electrical Exhibition of 1881; a little Trouvé motor works the screw. Now you see a picture of the boat "Electricity" (Fig. 15), and the

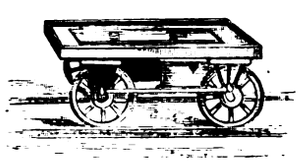

FIG. 14.

rate at which these boats are propelled is pretty considerable. There is a diagram on the table of the electric launch recently tried at Havre by the French navy; it is not a very elegant looking boat, but I believe it goes with great velocity, and gives satisfaction. I have had the pleasure of going up the Thames in an electric boat made for the Duke of Bedford, and I have been up the Danube in another electric boat. I am looking forward to the time when we may have electric boats on the Thames. It only wants some enterprising firm to establish machinery at charging depots at Teddington, Reading, and other places, to enable boats to be propelled by electricity.

All the applications of electricity that I have shown you have been by way of peaceful purposes, but the same power can also be used for the destruction of our enemies. I have here a miniature ship in a bath containing water. It represents a pirate vessel with its black flag and skull-and-crossbones ensign flying, sailing along seeking its prey. On the pan containing the water there are two marks, and when the boat gets between them I know it is in the vicinity of a submerged torpedo, and on sending an electric current the torpedo explodes, and blows up the ship and all its crew to destruction. That concludes the experiments that I intend to show you.

FIG. 15.

I have shown you various ways in which it is possible, by the proper utilisation of electricity, to economise labour; but there is always this fear—that if too many means of economising labour are introduced it may lead to idleness and evil. Still, when labour is saved in one direction it is given in another direction, and the result must evidently be beneficial in the long run.

I have brought before you some effects of one of the great powers of Nature, and I have shown you in these two lectures, in a very rough and hasty manner, how it is applied to useful

Digitized by Google

purposes. Every single purpose which I have shown you was in itself deserving of a lecture occupying a whole evening; but, however, to the best of my ability I have endeavoured to bring these matters before you, and I have been assisted in them by the very generous way in which others have come to my help. My friend, Mr. Lant Carpenter, has helped me considerably; Mr. Probert, Mr. Heather, Mr. Davenport, and others have all assisted. Mr. Immisch and Mr. Binswanger have been kind in their loan of motors, and our Chairman this evening has been the means of my carrying out several of the experiments, and others have come forward with a liberality that is really overpowering. I am only too glad to think that I have succeeded in keeping your attention together for these two nights, and, I hope, shown you something that you have never seen before, and which, I trust, may lead you to see a good deal more of in the future.

The CHAIRMAN proposed a very hearty vote of thanks to Mr. Preece for the lectures he had delivered. He said that those who hear lectures had very little idea of the enormous amount of labour and forethought, as well as devotion of time and energy, necessary to get together everything that is necessary for the lectures to work smoothly. The chairman added that they must not forget, as Mr. Preece had reminded them, to thank Mr. Lant Carpenter and others for the voluntary services they have rendered in order to make these lectures the success which they most assuredly had been.

Mr. PREECE acknowledged the vote of thanks, and the meeting then adjourned.

The engravings (Figs. 16 to 22) were prepared to illustrate Mr. Preece's description of the process of manufacture of incandescent lamps in Lecture I., when the various processes were shown in operation by Mr. Donaldson (see *Electrician*, May 4th, p. 737). Unfortunately the sketches did not reach us in time for insertion in that number. We append the following brief description, and must refer our readers to the issue of May 4th for a fuller account. In Fig. 16 we see the fine filaments of parchmentised cotton wrapped round a block of wood ready for carbonising. After being placed in a furnace and carbonised, the filaments are "mounted" (Fig. 17), *i.e.*, they are connected to platinum wires, placed in oil, or some hydro-carbon gas, and a strong current is passed through them; the hydro-carbon thus is decomposed, and carbon is deposited on the filaments, especially around their junction with the platinum wire, thus cementing the two together. In Figs. 18, 19, and 20 we have depicted the process of preparing the tube for the lamp-bulb and the blowing of the bulb. In Fig. 21 we see the finished bulb ready to receive the filament. The mounted filament is now fixed in the glass globe, and the platinum and glass are fused together. The next process is to exhaust the bulb, and seal it up, and in Fig. 22 is the finished lamp with a possible life of 4,000 to 5,000 hours before it.

THE PHYSICAL SOCIETY.

At the meeting of this Society on Saturday, May 26th, Prof. AYRTON read a note by Prof. PERRY and himself, of which we have prepared the following abstract:—

"On the Governing of Electromotors."

In 1882 the authors worked out and published a method of maintaining constancy in the speed of an electromotor with a varying load, based on a combination of a motor which converted electrical into mechanical energy with a brake dynamo which reconverted the surplus mechanical energy into electrical energy.

After passing through various stages of development the arrangement finally adopted consisted of an electromotor having the field-magnet wound with a shunt and a series coil traversed by the current in opposite directions, so that the magnetisation of the field-magnet was that due to the difference in the number of ampere turns in the two coils.

This method had been re-invented in France by M. Deprez, and in America by Mr. Sprague, and had been submitted to exhaustive tests by Dr. Frölich; but the authors had not attempted to develop it further owing to the great defect of causing a considerable waste of power, which was necessarily involved in the use of a demagnetising coil. The original method was applicable either to the supply of constant current or of current at constant potential difference, but the authors noticed recently that in the former case the original equations were capable of giving a solution in which the demagnetising coil was dispensed with, and therefore a constant speed obtained, together with the high efficiency of a well-made dynamo. As it was only required to determine whether or not a certain combination would give a certain required result, the equations are simplified by neglecting saturation, and, therefore, the results obtained for critical speed, &c., cannot be applied without correction to actual practice.

Let E be the back E.M.F. in the armature of a motor running at a speed of n revolutions, p a term depending on the permanent magnetism of the iron of the field-magnet, S the current through the series coil, q the number of turns in it, Z the current through the shunt coil, and t the number of turns in it.

Then
$$E = n(p \pm q S \pm t Z) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$
the upper or lower sign being given to either the second or third term, according as the current in the corresponding coil assists or opposes the permanent magnetism.

Let S and Z be the resistances of the series and shunt coils respectively, a the resistance of the armature, and A the current in it. Then for a short shunt machine
$$E = Z z - A a \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$
and for a long shunt machine
$$E = Z z - A (a + s) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$
and in both cases, if C is the constant current supplied to the motor,
$$C = A + Z \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$
In the former case C = S, so that equations (1), (2) and (4) give
$$n\{p \pm q C \pm t(C - A)\} = (C - A) z - A a \quad . \quad . \quad (5)$$
In the latter case S = A, so that equations (1), (3) and (4) give
$$n\{p \pm q A \pm t(C - A)\} = (C - A) z - A (a + s) \quad . \quad . \quad (6)$$
When n and C are given, equations (5) and (6) have to be satisfied for all values of A.

Thus for a short shunt
$$\pm n(-t A) = -A(z + a) \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$
and for a long shunt
$$\pm n(q - t) A = -A(z + a + s) \quad . \quad . \quad . \quad . \quad (8)$$
Now n, t, q, z, a, and s are all necessarily positive, and t is always larger than q, so that the positive value of t in equation (1) is the one which must be taken—that is, whatever the arrangement of the series coils, the shunt coil must be a magnetising and not a demagnetising one. In the Paper on "Electromotors and their Government," by the same authors in Vol. XII. of the *Journal* of the Society of Telegraph-Engineers, they had already shown that the solution for constant current was a shunt-motor with a series demagnetising coil; but the authors point out that in a standard English treatise the only solution for constant current with which they are credited is the *impossible* one of a series motor with a shunt demagnetising coil, which would require the speed to be negative, or the armature rotation to be reversed, which would simply mean the combination of a shunt-motor with a series demagnetising coil.

In another important English work the method is given correctly; but it is stated that it would not work, because if a greater load were put on the motor would slow down, the back E.M.F. would decrease, and less current would flow through the shunt coil, thus weakening the field-magnet, and therefore further diminishing the speed of the motors, which would thus be brought to rest or possibly reversed. But it is now well known that a weakening of the field does not imply a diminution of speed; and the explanation of the apparent anomaly that to maintain the speed of a motor constant the field must be weakened when the load is increased is, of course, that the power depends on the current through the armature as well as on the strength of the field, and when the latter is diminished the former is much increased.

For a simple shunt motor supplied at constant potential difference V, $V = Z/z$, $E = Z z - A a$, and also
$$E = n(p + t Z) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$
so that
$$n\left(p + t\frac{V}{z}\right) = V - A a \quad . \quad . \quad . \quad . \quad (10)$$
The left-hand side of this equation is constant when n and V are given, while the right-hand side is variable as A depends on the power given out by the motor. A solution which makes the equation true, independently of the value of A, is clearly the well-known one of making a very small, but the authors have elsewhere given reasons against making the resistance of the armature of a motor as small as that of a dynamo armature. If this solution is rejected, a negative term proportional to A must be added on the left-hand side, and this is most simply done by adding a series demagnetising coil, when equation (9), and (10) in its more general form, become respectively
$$E = n(p - q A + t z),$$
and
$$n\left(p - q A + t\frac{V}{z}\right) = V - A(a + s).$$
The latter will always be satisfied for any value of A if
$$n = \frac{a + s}{q}.$$
When the supply is a constant current the equations for a simple shunt motor are
$$E = n(p + t z)$$
$$E = Z z - A a$$
$$C = A + Z$$
which give
$$n\{p + t(C - A)\} = (C - A) z - A a \quad . \quad . \quad . \quad (11)$$
which will always be satisfied if
$$n = \frac{z + a}{t} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$
so that a series demagnetising coil is *unnecessary*. Substituting this value of n in equation (11) gives as the current for which the motor governs
$$C = \frac{n p}{z - n t} = -\frac{n p}{a}.$$
The terminals of the motor must therefore be reversed. This will reverse the currents round the field-magnet, but it must not reverse the residual magnetism, or p would also become negative. The core of the electric magnet must, therefore, be of steel so strongly magnetised that the shunt current does not reverse the polarity, and the permanent magnet and rotating armature will form a brake dynamo, while the shunt coil and the armature will form the motor. This is simply one of the solutions (theoretical, of course, not practical), given in the Paper referred to.

To obtain a practical solution, alter this equation so that when the speed equation (12) is satisfied, equation (11) gives a positive value of the current, which may be done by adding to the right hand side of the equation (11) a positive constant term e, numerically greater than $n p$, for then
$$n = \frac{z + a}{t} \quad \text{and} \quad C = \frac{e - n p}{a}$$
for all values of A.

This may be effected by introducing accumulators of E.M.F. e into the armature circuit, joining them up in such a manner as to assist the main current C.

The resistance of the armature will then be increased by a value a', the resistance of the accumulators, so that the final equations to determine the speed and the constant current at which the motor governs will be
$$n = \frac{z + a + a'}{t} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$
$$C = \frac{e - n p}{a + a'} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14$$
The solution is a practical one, and, moreover, it does not require many accumulators, for $n p$, the back E.M.F. of the motor, due to the residual magnetism alone, will be small if the core of the field-magnet is of soft iron, and a and a' need not be large, so that C can be made as large as required, without giving a very large value to e.

The essence of this method consists in combining a shunt motor with a store of electric energy in the armature circuit, this energy being, as shown by the equations, automatically dealt out to assist the motor exactly in proportion to the power required to keep the speed constant as the load is varied.

Digitized by Google

The store is easily maintained by reversing the connections of the accumulators when they are disconnected from the motor and the motor is at rest, and leaving the accumulators to be charged, without supervision, by the constant current which is continually supplied.

Prof. RÜCKER observed that the method was certainly novel and extremely interesting. He would like to know, in case the motor did much work, what would be the relation between the number of accumulators required and the amount of work, and whether any inconvenience would be experienced in replacing them.

Prof. AYRTON, in reply, pointed out that accumulators will discharge, at a fairly steady rate, for 7 or 8 hours, and the discharging current is less than the charging current, so that no difficulty would be experienced in running the motor for 15 or 16 hours a day with the single set of accumulators, though if required to run continuously two sets would, of course, be required.

The SECRETARY then, in the absence of the author, read a note by Prof. S. P. THOMPSON,

"On the Formula of Bernouilli and of Haecker for the Lifting Power of Magnets."

Bernouilli's empirical rule ("Acta Helvetica," III., 233, 1758) is given by the formula

$$P \propto \sqrt[3]{W^2}$$

where P is the lifting power or pull exerted by the magnet in contact with its keeper, and W the mass of the magnet. Haecker (Poggendorff's *Annalen*, LVII., 321, 1842) wrote the formula

$$P = a\sqrt[3]{W^2},$$

and taking the German pound as the unit of mass found that a varied, according to the quality of the steel and the intensity of the magnetisation, from 8 to 10, and double these values for horse shoe magnets; so that a steel horseshoe magnet weighing one pound would lift from 16 to 20 pounds.

The formula was found to be fairly correct for magnets weighing from 1·120 pounds up to 40 pounds.

Van der Willigen ("Sur le Magnétisme des Aimants artificiels," par V. S. M. Van der Willigen, Haarlem, 1878) repeated the investigations with Haecker's own magnets and others, and arrived at the formula

$$P = b\,K\sqrt{A}\cdot\sqrt[4]{\frac{L}{\sqrt{A}}}\cdot\frac{L}{l},$$

where b is a constant depending on the quality of the steel and the intensity of magnetisation, K the perimeter of the polar surface, A its area, L the distance between the poles, and l the mean of the interior and exterior lengths of the bar.

For similar solids $K\sqrt{A}$ is proportional to the surface A, so that according to this formula the lifting power of similar magnets is proportional to the polar surface multiplied by a correcting factor depending on the proximity of the poles.

Van der Willigen found that b, which is virtually identical with Haecker's a, varied from 19·5 to 22·5.

Now in similar magnets, the linear dimensions are proportional to the cube root of the mass, and the polar surface is proportional to the square of the linear dimensions.

Therefore, for similar magnets, both formulæ mean simply that the lifting power is proportional to the polar surface, which we know from Joule's and subsequent researches to be approximately true for equal intensities of magnetisation.

In the light of more recent researches on the magnetic induction in closed circuits, the same conclusion is arrived at, for if the magnetic induction B has been carried to an equal degree in the metal, the tension in dynes per square centimetre, at any point of the circuit, is (Maxwell's "Electricity and Magnetism," Art. 643)

$$T = \frac{B^2}{8\pi},$$

and the element of pull over the area d A is

$$d\,P = T\,d\,A = \frac{1}{8\pi}B^2\,d\,A;$$

so that

$$P = \frac{1}{8\pi}\int B^2\,d\,A,$$

which can be determined if the law of distribution of magnetic induction through the cross-section is known. Assuming this to be uniform, we have

$$P = \frac{1}{8\pi}B^2\,A.$$

This formula gives a convenient method of determining B from measurements made of the pull on a given polar surface, the ormulæ becoming

$$B = 5000\sqrt{\frac{P\text{ kilos}}{A\text{ sq. cm.}}} \qquad B = 1317\sqrt{\frac{P\text{ lbs.}}{A\text{ sq. in.}}}$$

The a of Haecker's formula may therefore be considered to be simply proportional to the square of the magnetic induction through the surface of contact, or

$$a = \frac{1}{8\pi}B^2 d^2 c,$$

where d is the density of the steel, and c the ratio of the polar surface to that of the face of a cube of volume equal to that of the magnet.

According to Haecker, a is twice as great for a horseshoe magnet as for a bar magnet; according to Van der Willigen, three or four times as great: showing that in the former case, owing to the great resistance offered by the long return path through air of the tubes of magnetic induction, the steel magnet was only able to produce a much smaller induction (the ratio 1 to $\sqrt{2}$, according to Haecker's results) than when the circuit was closed.

Lifting power being proportional to surface, with a given intensity of magnetic induction, explains the greater lifting power of small magnets in proportion to their weight, without assuming, as is often done, that small pieces of steel can be more highly magnetised than large ones.

For electro-magnets a simplification is introduced by the principle of the magnetic circuit.

Assuming the material of the core and armature to be similar in permeability and cross-section, B is independent of the value of the latter, and is given by the formula

$$B = \frac{4\pi S i \mu}{10\,l},$$

where μ is the permeability, l the total length of the magnetic circuit, i the current in amperes, and S the number of convolutions in the coil.

For values of B between 8,000 and 16,000 μ for a certain quality of good wrought iron is approximately given by the formula

$$\mu = \frac{16000 - B}{3{\cdot}2},$$

which gives for the approximate lifting power of such an electro-magnet

$$P\text{ kilos} = A\text{ sq. cm.} \times \left(\frac{3{\cdot}2\,S\,i}{S\,i + 2{\cdot}56\,l.\,cm.}\right)^2,$$

or

$$P\text{ lbs.} = A\text{ sq. in.} \times \left(\frac{12{\cdot}2\,S\,i}{S\,i + 6{\cdot}5\,l.\,in.}\right)^2.$$

The net result of this Paper is that Haecker's formula is merely a clumsy way of stating that the lifting power of a magnet is (for equal intensity of magnetisation) proportional to the polar surface.

Prof. AYRTON observed that he would have liked to ask Prof. Thompson how far he had considered the surface between the armature and the magnets, as he thought there would be a good deal of resistance at the junction. It was certain that a great difference could be produced in the lifting power by merely scraping the surfaces, without any alteration in the air-gap. He mentioned that the curious fact had been observed that while an ordinary electro-magnet only requires a small force to detach the armature after the current had stopped, it was found that if the pole-pieces were carefully scraped a very large force was required, and if the armature were left in contact with the magnet, the force required to separate them would continue to increase with the time during which they were left in contact, after the current had been turned off. This increase had been observed to continue for a month or longer.

A Paper by Messrs. Gee and Holden on

"Experiments on Electrolysis"

was also read. We shall give an abstract in a subsequent issue.

FIFTY KILO.-WATT GOOLDEN-RAVENSHAW DYNAMO.*

The present tendency in dynamo building is in the direction of increased size. Some five or six years ago, when the manufacture of dynamos was with most firms but an infant industry, machines capable of running 100 or 200 glow-lamps were considered fairly large, and constituted productions of which the manufacturer was justly proud. Compared with the original Gramme machines, a 200-lighter was undoubtedly a great achievement; but at the present time such a machine is considered almost a toy as compared with the powerful dynamos which are now made as regular articles of commerce. The three machines required for the Bradford in-

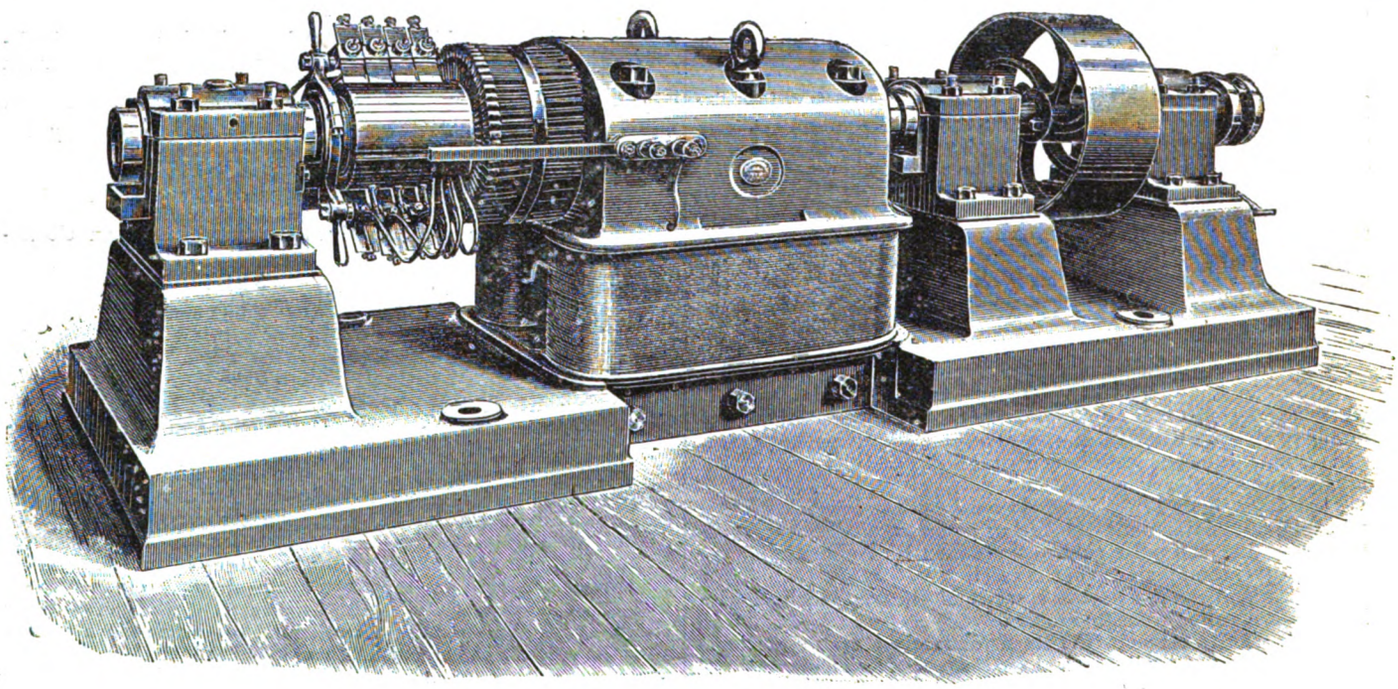
* From *Industries*, May 25th.

Digitized by Google

stallation, for instance, will each have an output of 85 kilo.-watts, and we recently saw in a Continental works two machines in course of construction, each for an output of 120 kilo.-watts; and 100 kilo.-watt Edison machines for central station lighting are by no means unusual at the present time, to say nothing of alternating-current machines, the power of which is expressed by thousands of glow-lamps. In most cases large dynamos are direct-driven by special engines; but occasionally belt driving is resorted to, and we illustrate above a belt-driven machine made by Messrs. Goolden and Co., of Halifax, to the design of Mr. W. H. Ravenshaw. This machine is interesting, not only on account of its size, but also because it contains several contrivances which the increase of size rendered necessary.

As will be seen from the illustration, the machine is of the "over" type, with the yoke in the bed-plate and the armature above. It has an output of 500 amperes at 102 volts pressure when driven at 375 revolutions per minute. The armature is of the drum pattern, with internal ventilation, and the conductor consists of six 192 mil. wires in parallel, there being 120 conductors counted all round the armature. Its resistance is ·0066 ohm, and the resistance of the field-magnets, which are plain shunt-wound, is 6·3 ohms. The total useful induction through the armature core is about 2,300 English lines. The armature core consists of the usual iron discs, which, however, do not fill the whole interior, but are of the same dimensions as used by Messrs. Goolden and Co. for Gramme armatures, and are mounted upon the spindle in the same manner. There is thus gained an internal space for ventilation, and a sleeve is fixed over the shaft on the pulley side, leaving an annular space for the admission of air, which is drawn through the armature by means of a fan placed between the commutator and the armature core. By an ingenious method of winding the ends of the armature are left flat, and not bulging out as in the Hefner-Alteneck winding, thus economising in length of wire. The magnet cores are of wrought iron, bolted to the bed-plate, and the pole-pieces are of cast iron, fastened to the magnets by strong bolts, as shown in our illustration. The exciting coils are made with their long sides slightly bulged, so as to cause the wire to lie tightly, and at the same time provide ventilation between the surfaces of the magnets and the internal surfaces of the exciting coils, a suitable slot being left in the flange of the pole-piece, as shown.

In this machine a special device has been introduced for giving to the armature a definite to and fro motion lengthwise, in order to keep the bearing surfaces and the surface of the commutator in good condition. It will be remembered that in some of the early Edison machines a similar rocking motion was introduced by means of a spring pressing against the end of the shaft, and several dynamo makers have adopted the rule to allow the shaft a little play endways between the bearings, relying on the side motion of the belt to keep the armature rocking to and fro. This plan, although it works fairly well in certain cases, is not always satisfactory. The armature is often found to rock too violently, and thus produces knocking between the collars on the shaft and the ends of the bearings. To overcome this difficulty and yet obtain the advantage of a variable position of contact between the brushes and the commutator, Mr. D. Halpin has devised a special brush holder and gear by which the brushes are slowly shifted backwards and forwards in a direction parallel to the spindle; but a more simple plan is to make the clearance between the collars and bearings larger than the distance through which the armature rocks. The field-magnets exert an attraction upon the armature in the direction of the spindle if the centre of the core of the armature does not exactly coincide with the centre of the pole-pieces. If the armature be shifted out of this position of symmetry, the field-magnets will pull it back, and the force thus exerted is quite sufficient to limit the oscillation to either side of this normal position. This plan answers well in small and medium-sized machines, but for very large machines it is obviously better to prescribe the path through which the armature shall rock, and this is done in the present design in the following way:—To the end of the shaft outside the bearing is fixed a cast-iron disc, and between this and the bearing there is loose on the shaft a second cast-iron disc, with an inclined face. On a spindle at right angles to the shaft, and secured to the fast disc, is a loose roller touching the opposed surfaces of the two discs. The external diameter of these discs is slightly different, and against their periphery is pressed, by means of a spring, a paper roller running loose on a stud. The centre of the armature core is set slightly back as compared to the centre of the field-magnets, so that the magnetic attraction tends to pull the whole armature forward towards the commutator bearing, thus keeping a certain pressure between the two discs and the roller. It will now readily be seen that, as the armature revolves, motion is imparted to the paper roller by the fixed disc, and the paper roller in turn causes the loose disc to revolve at a speed which is slightly different from that of the shaft and fixed disc. The diameters of the two discs are so chosen that the relative movement of the loose disc against the fixed disc is two complete revolutions per minute, and the whole armature receives, therefore, two complete out and in motions per minute, by which means the position of the brushes on the commutator is continually varied lengthwise, and scoring is entirely prevented. The longitudinal motion has also the advantage of preserving the bearing surfaces in perfect condition. The total weight of the machine is six tons.



The Goolden-Ravenshaw Fifty Kilo.-Watt Dynamo.

ALTERNATING v. CONTINUOUS CURRENTS.*

BY M. M. M. SLATTERY.

A few days ago when I had the honour of receiving an invitation to read a paper before this club to-night, relating to the alternating system in parallel arc, to be in reply to Mr. Leonard's Paper,† I felt, understanding Mr. Leonard's proclivities, that the usual stereotyped attack would be made upon a system which has alike elicited

* Paper read before the Chicago Electric Club, March 19th.

† See *The Electrician*, page 604, April 6th, 1888.

Digitized by Google

the admiration of those who have disinterestedly given the subject some thought, and the most rancorous feeling on the part of those whose business has been placed somewhat in the background by the rapid developments which have taken place in this comparatively new field of electric lighting. In a moment of unguarded enthusiasm I accepted the invitation. As some of you may know, I am practically engaged in the alternating branch of electric lighting, and my time is so much occupied therein as to almost entirely preclude me from having any to either write or read papers. I regret, therefore, that in this short Paper I shall not be as comprehensive as I should wish, and will principally confine myself to replying to some of the salient points in Mr. Leonard's Paper.

We are told that the following are the sum total of the vital factors in a general supply system of electric energy, viz. :—

1st. Cost.
2nd. Economy (efficiency and depreciation).
3rd. Reliability.
4th. Safety to life.
5th. Variety and value of the possible sources of revenue.
6th. Effects upon existing property.

The factor of distance over which you have to transmit the electric energy is conspicuous by its absence, not being considered of sufficient importance to be enumerated in the list ; we shall see presently of what value this factor is. Of course Mr. Leonard, as is customary with advocates of the low-tension systems, starts out with explaining the transcendent merits possessed by the three wire systems, and expresses in the usual terms the 33 per cent. saving over the two-wire system.

In the Paper read by Mr. Leonard elaborate tables of figures are given, into which I will not attempt to follow him in detail to-night. It would only weary you, and, as you are aware, if the premises are once granted, almost anything can be proved by figures. All I would say is, examine those figures yourselves, but do not *assume* that the *data* are correct.

It is a very ingenious rhetorical device to take the cost of the Edison system for distribution over a small area, and compare it with the cost of the alternating system over a small area, and thus show that, taking price of converters into consideration, the Edison is the cheaper. This is avoiding the question. The chief claim made for the alternating system is that it can reach customers and supply a market that the low tension *never* can.

Another point to which I would call your attention is this : Mr. Leonard assumes the cost of copper to be 16 cents per pound ; *he had to* so as to bring his estimates at all within bounds. Now, we all know that the price of copper is more like 25 cents than 16 cents. The variation in the price of copper affects the low-tension system much more seriously than it does us—another point in favour of the alternate-converter system. It may be said, "Yes, but you have to use copper wire in your converters as well as your lines." True, but only to a limited extent ; the cost of the converter is also largely made up of the iron and the labour. The quantity of wire in a good converter is but small.

Another reason why I do not care to take up your time with a detailed discussion of these figures and tables is that the field has been pretty well covered by Mr. Stanley in a Paper recently read by him in Boston, and also for the reason that Prof. George Forbes, who is recognised as one of our best authorities, has said with regard to the theoretical economy of the three-wire system that "this may suit American financiers, but is *not* electrical engineering."

Mr. Leonard is not warranted in assuming a thing in order to enhance the value of his claims. He says we may look forward to improvements in the incandescent lamps which will result in 30 per cent reduction in the cost of conductors in the three-wire system. I have been engaged in the manufacture of incandescent lamps for some twelve years, and as I have to follow the subject up closely, I trust I ought to know a little about the improvements which have been made in the past and the possibilities ahead for the future, and I find that for the four years just past very little has been done towards improving either the life or the efficiency of incandescent lamps. A so-called improvement by a well-known company, the Edison, has lately been trumpeted in every direction. Why, Swan has been making such a lamp in England for some five years; and so could this same company have made them if they only employed methods which are equally within the reach of all.

The reason for this recent claim is obvious—it is an offset to the large number of lamps per horse-power claimed for the induction system.

With regard to this claim put forward on behalf of the Edison Company of being able to obtain twelve 16 candle-power lamps to the horse-power, I will not dispute it, but simply say that the gentleman who was for four years the mechanical engineer of the Edison Electric Light Company has, within the past six months, given sworn testimony in these words :—"In the direct-current, central station system the maximum which, to my knowledge, has so far been obtained is between six and seven lamps to the horse-power."

Now, gentlemen, a 100-volt lamp, such as is the Edison, could certainly be made which would run, say, 12 to the horse-power, yes, 15 or 20 ; but what would the life of those lamps be ? In all probability, as far as our present knowledge goes, *very brief*. I prefer, in a case like this, to reply upon an absolute statement of fact rather than upon any promises or guarantees or possibilities.

The limit of voltage at which a lamp can be made so as to have a reasonable life has, it seems, been reached in its upward direction at about 110 volts. It was anticipated a few years ago that a high-volt small-current lamp was the great desideratum. Scarcely any progress in that direction has, however, been made for some time, as I have just said, and the tendency, in fact, now appears to be the other way, *i.e.*, towards low-resistance lamps—say 50 volts.

The continuous-current system is far more susceptible to heavy fluctuations than the alternating, owing to the total absence of automatic regulation in the former, and, when it is remembered that the light intensity of an incandescent lamp does not vary as the potential difference at its poles, but in a much greater ratio, it will be readily understood that the fluctuating system has a much more hurtful effect upon the delicate incandescent lamp than the non-fluctuating system. I am supported in this statement not by the opinion, but by facts deposed to by the gentleman referred to. He says :—"The usual percentage of loss in the carrying wires of a direct-current system is 15 per cent., and even with this heavy loss the carrying wires attain a stupendous weight. The practical result from the introduction of this loss in the main wires of the direct-current system is that when such a plant is running fully loaded the E.M.F. at the dynamos will be 15 per cent. higher than at the lamps, whereas, when only lightly loaded, the difference in E.M.F. at the dynamos and lamps runs down to a much smaller figure; therefore, in order to maintain the lamps at a uniform brilliancy, the E.M.F. at the dynamos must be carefully watched and adjusted to suit the varying requirements of the load, as in the absence of such care the brilliancy of the lamps will fluctuate and give rise to serious lamp breakage. This regulation of the E.M.F. is accomplished partly by regulating the field-magnets of the machine and by the introduction of artificial resistances in the main carrying conductors. The attention to secure these results is expensive, and the devices for accomplishing them are very costly."

There is another matter in connection with central station arrangements which, it seems to me, disposes of the question of the relative commercial merits of the two systems in a conclusive manner, and that is this :—The advocates of the low-tension systems admit that as far as actual wire goes, the 1,000-volt distribution is more economical than is the 100 or 200-volt—that is a palpable matter. But, say they, in addition to the danger and other objectionable features of your plan, the cost of your converters is so great as to neutralise whatever advantages you may have in this way. Without going into that point for the moment, it will be seen that the converter itself costs no more whether the current supplying it comes from 1,000 or 10,000ft. away ; that being so, the difficulty which stares the Edison system in the face is the practical necessity of picking out for their central station about the most expensive piece of real estate in the district to be lighted. They *must* be near the centre ; they say so themselves. On the other hand, with the high-tension induction system, you may have your central station in the outskirts of the town on cheap land, perhaps on a canal bank or railway siding, so as to unload your coal direct into your boiler room, which may itself save many hundred dollars per annum, while the extra length of the comparatively small conductors would be but a bagatelle compared with the real estate investment in the centre of the town.

That I am not speaking off the book in this matter will be seen when I quote a passage from a document issued by the Edison Company, entitled "Information to Agents," and relating to the desirability of centrally locating the station. It is as follows :—

"*Note.*—In a given district to be lighted, the best conditions of economy in street installation are fulfilled when the station is located in the centre of the district. If the station is moved one-quarter of a mile away from such centre the cost will be about doubled. If the station is moved one-half mile away from centre the cost will be about quadrupled. . . . There need be no hesitation in locating it in the most central locality. A few hundred dollars increase in cost of lot will often save thousands in cost of street installation."

The reasons for the prominence which a 50-volt lamp is now acquiring are four-fold, namely, cheapness in manufacture, efficiency, reliability, and that while it is the lowest limit in volts that we should allow ourselves (for distributing reasons) it exactly suits the most efficient construction of converter.

Digitized by Google

The fewer the number of turns of wire in a converter the better, within proper limits, and as in a 50-volt converter we have only half the number of turns that we should have in a 100-volt, the advantages of the 50-volt lamp for our purpose will be apparent; the fact also is that, while the manufacture of the 100 and 110-volt lamp has received the greatest attention by manufacturers for obvious distributing reasons, the 50-volt lamp has received comparatively little notice, not being recognised as a factor in a general system of distribution.

The Fort Wayne Jenney Company are now making a 40-watt 16 candle-power 50-volt lamp. This lamp could just as well have been made long before this, but there was no demand for it such as there now exists. If such improvements as Mr. Leonard predicts for the 100-volt lamp are likely to take place, and the ratio of the present efficiency of the 100 and 50-volt lamps holds good, we might look forward to a corresponding increase of efficiency which would enable us to reduce the cost of our converters in nearly the same proportion—that is to say, the cost of a 40-lamp converter would be very little more than for the present 25. There would also be the proportional saving in the cost of interior wiring.

Much has been said and written by the opponents of the induction system about the respective first cost of an induction installation and a low-tension continuous-current installation, viz., that the low tension is cheaper for very short distances.

This sounds very much like a man who had a continually growing business requiring an engine saying that a small engine was cheaper for him than a larger, because the smaller engine just then met his requirement, and after a little time he finds it necessary to dispose of his small engine at a considerable discount for a larger one that will be more adequate to his growing needs. Why not put in at the first that system in which will meet any and every illuminating requirement for all time, both at points near to and remote from the source of generation.

I do not know whence the information has been derived, but the theory does exist that with a reduction of the load in the multiple arc induction system there is not a proportional reduction of the energy supplied to the circuit, and that consequently the loss of energy in the line does not decrease proportionately with the load. While this theory would and does apply to a series system of transformers it does not apply to the multiple arc induction system, the latter standing in the same relation with regard to the energy supplied to its circuit as the low-tension multiple arc. Upon another occasion I trust to have an opportunity of bringing forward mathematical deductions and power curves incontestably proving this fact.

No doubt a system cannot be considered a reliable one unless you are able to multiple arc your dynamos; well, we are able to do this. It used to be regarded as difficult, but, gentlemen, with a great many of those apparent difficulties we need only to understand their nature to overcome them, and, although at the present moment we cannot couple as many together as we should wish, I venture to say that by the time such a necessity arises we shall be ready to meet it. It is stated that we cannot multiple arc dynamos economically, as occasionally one dynamo will shift the load and the other dynamo not only will take it, but will drag the other. In an incomplete system this is just what takes place, but a device is brought into operation that varies the speed of the engine according as any variation therein takes place, thus maintaining the speed of all the dynamos coupled in multiple and their potentials uniform.

A good deal has been said from time to time as to these dangers of the alternating system, and notwithstanding the repeated explanations and statements of those who are acquainted with alternating currents and their use, yet only a week or two ago Mr. Leonard in his Paper read before this club attempted to resuscitate this scare, which we supposed had been forgotten.

Prof. Elihu Thomson has publicly stated that he has taken a 1,300-volt alternate current without serious inconvenience. I have myself, as have several of my friends, taken 1,000 volts, and in all the cases with which I am acquainted nothing more than some temporary discomfort followed.

The most serious case of which I ever heard was that mentioned by Mr. T. Carpenter Smith, at the Boston Convention. In that case the man was not permanently injured, although under the influence of the current for quite a considerable time. Although I would not go so far as to recommend the use of the 1,000-volt current as a morning beverage, yet it is absurd to let the impression now, as to the lamp, go abroad that it is necessarily or even probably fatal.

We recognise the fact that an electric current of 200 volts is less dangerous than one of 1,000 volts—of course we know that. Does it therefore follow that we shall throw to the winds every advantage that this higher pressure gives us? Because a buggy is less dangerous than a locomotive do we therefore abandon railroads? Because an arc-light system requires more than 100 volts pressure, are we, therefore, to abolish every arc light in the country? These questions answer themselves.

There is nothing to prevent us placing our lamps upon existing gas fixtures, unless it be ignorance or not employing the proper precautions to render the work absolutely safe. It is suggested by some that in order to prevent the high-tension primary current being dangerous to life, in the event of a leak between the primary and secondary coils taking place, to ground the secondary; then if a leak took place from the high-tension circuit to the low-tension circuit, and there happened to be a ground somewhere else on the primary circuit, no harm whatever could occur to a person taking hold of the terminal of an incandescent lamp and at the same time touching a gas fixture. While this arrangement makes the use of the lamps by the customers absolutely safe it subjects the entire system to a strain on the insulation which I do not think is quite wise, and, instead of grounding the secondary, I think the better plan would be to ground a sheathing of metal interposed between and carefully insulated from the primary and secondary. So far as safety to life is concerned this is just as good, but has the recommendation of not subjecting the insulation throughout the system to any strain whatever, and has been used for some time with satisfactory results.

A charge laid at the door of the alternating system is that of want of reliability, and a few small breakdowns which have occurred are exaggerated to a considerable extent by those interested in other systems. Such matters are liable to occur in all new installations, the Edison not excepted. They are simply boyish indiscretions, errors of youth, and not faults of the system as such. In a very short time the experience we have gained in this respect will bear due fruit, and the alternating be just as reliable as the continuous system. In the absence of gross carelessness there is no reason to the contrary, and, indeed, down to the present time even, accidents have been rare.

With regard to an alternating-current dynamo of 1,000 volts being more liable to burn out than a low-tension continuous-current dynamo of 110 volts, and that the depreciation of the latter is less than the former, this seems to me to be nonsense. Understanding the nature of the work that a dynamo has to do, and with proper experience in construction, there should exist no reasonable doubt about making one dynamo to work as reliably as the other; this is purely a mechanical matter, and the ingenuity of our mechanics is equal to any such emergency as that. And as to depreciation, I venture to say—in fact, I know—that the armature of an alternate-current dynamo of the kind I have had any experience of, at full load, does not arrive at anything like the temperature a low-tension Edison dynamo does under the same conditions; and we all know what high temperature in a wire has to do with the deterioration of its insulation. Furthermore, by reason of the small quantity of wire necessary in the armature of the alternate-current dynamo (for instance, in an 800-light machine made by the Fort Wayne Electric Light Company, there are only 20lb. of wire), we can afford to occupy more space, and thereby have less crowding of the wire; thus we have an opportunity of increasing our insulation in proportion to E.M.F. required.

There has been some little uncertainty about the action of converters in respect to the fuses enclosed in the converter box frequently and mysteriously melting. This, however, I find is attributable to the temperature of the converter at full load not being calculated as a factor with the current for the melting point of the fuse, and I think it will be much better us for to be satisfied with an external double pole fuse at the point of junction of the primary coil with the primary line, and a double pole fuse on the secondary circuit as close to the converter as possible; this arrangement thoroughly protects the system, and a possibility of a failure of the converter becomes a very remote one.

It is said that the operating of motors by alternating currents is not a success. Well, it may be admitted that at the present time the commercial operation of alternate-current moters has not attained very large dimensions; but who is presumptuous enough to say that, when the present systems of alternate-current supply are as old as the continuous, there shall not be as many and as satisfactory motors running on alternate currents as on continuous? Is it for any gentleman connected with the Edison Company to stem the river of invention, to say that the acme of perfection is reached in the triune system of that august body, and to thunder forth electrical excommunication on all heretical expounders of the faith? I trow not. Alternate-current motors have been made which have in them the elements of success, and the subject is daily attracting more and more attention from some of our most talented workers in that direction, both practical and theoretical, as examples of which I may mention the valuable Paper read quite recently by Dr. Louis Duncan before the American Institute of Electrical Engineers,* and the earlier one read some months ago by Prof. Elihu Thomson,† with which no doubt most of you are familiar.

---

Digitized by Google

The mere fact that motors will work on an alternate current is of course well known. The difficulties are in the regulation, the degree of economy, and other matters. But a *difficulty*, gentlemen, is merely a "thing to be overcome." That is what difficulties are for. *These* will be overcome, as have so many others in the grand field of electrical progress. Why, I remember hearing Dr. Werner Siemens say with his own lips that it was hopeless to expect to make a dynamo with a higher efficiency than 50 per cent. ! He lived to see himself mistaken, and perhaps others may do the same. Not ten years ago the "divisibility of the electric light," as it was called, was ridiculed as the chimera of an enthusiast's over-heated imagination, but nevertheless where are we to-day?

The objection to the alternating system on this motor question is based on the assumption that it is a desirable thing to operate motors on the same circuit as lights. Now, although at first sight this would seem to be the case, and although I am not prepared with any formal objections to that course, yet I do know of one company that has been running motors on the same circuit as lights, but are now running a separate motor circuit instead, in addition to their lighting circuit. So that there is such a difference of opinion on the question that it cannot be fairly disposed of by any *ex cathedra* utterances of the advocates of any particular system.

One curious fact, which I think is not very generally known, though the information is public property, would seem to show that the Edison Company do not regard the alternating systems as such insignificant opponents as they would have us believe. The advocates of the Edison system profess to regard all these alternating-current high-tension systems as inferior to their own, and as almost beneath contempt; yet, singularly enough, I find that 12 months and more ago the Edison Electric Light Company of New York thought enough of one of these systems—the Zipernowsky—to acquire the exclusive right in North America to use all the patents on that system, and to obtain an option to purchase for $20,000 these Zipernowsky patents, so soon as they are granted a broad controlling claim in a United States patent, on transformers for alternating currents used on the multiple-arc principle. To say the least, it is strange that a company should be willing to pay such a large sum of money for so worthless a system as they pretend that it is.

Does it not rather show that they are more frightened than they say, and are providing for themselves a *locus penitentiæ*? I think it does.

It may be considered that my remarks sound like a direct attack upon the Edison Company's system, but I have admitted wherein the induction system is weak, and only claimed such advantages for the latter as are warranted by fact; and when we know of cases where after large installations had been put in and paid for—such, for example, as that of Tyrone, Pa.—the investors found upon careful consideration of the question that they could make more money by setting aside their original investment and change over from low-tension continuous (three-wire at that) to high-tension induction, then I have not spoken too strongly. But, gentlemen, whatever I or anybody else may say in favour of one system and in condemnation of the other system will, from a commercial point of view, affect the subject in dispute very little, and we may rest assured of one thing—that the public at large, whose business it is to study these questions, have discrimination enough and practical knowledge sufficient to enable them to make a wise selection. The respective systems, low-tension continuous and high-tension induction, are now before the public, and the ascertaining of their respective values is within the reach of those who desire to know them. They will perceive that claiming a thing cannot be done will not make it so, for they will see it being done, and the great question with the public will be, what does this cost, what profit can I make upon my investment? Be confident that the public will not go far wrong when the information it seeks is placed within its easy reach.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 19th*, 1888.

There has been considerable movement in electrical circles in New York during the last week. On Saturday evening an entertainment was given at the Electric Club, when Mr. E. T. Gilliland exhibited the latest form of Mr. Edison's phonograph, and read a Paper on the subject. There was a very large gathering, and the reproductions by the phonograph of the pianoforte, cornet and other musical instruments, as well as songs and ordinary speech, were excellently given, and were received with the utmost interest and enthusiasm. In point of fact, it would seem that the instrument has not gained very much in clearness of reproduction and articulation, but the apparatus has been greatly simplified and reduced in size, and has been rendered far more available for general use. One of the most striking exemplifications of its handiness was given in a small room fitted up like a printing office, where a compositor set type from phonographic dictation, starting the machine with a pressure of his foot to dictate a new sentence, stopping it and then starting it again. It will thus be seen that busy literary men, such as the editors of daily papers, can dictate their editorials or news paragraphs right into the phonograph, and have no other bother about it than the reading of the proof from the compositor's galley. In order to gratify the general interest in the subject the Edison Phonograph Company has had three or four of its instruments on exhibition all the week at the Club House.

During the present week the American Institute of Electrical Engineers has entered upon its fifth year, has had its election of officers, and has held its annual gathering. The new president, who was unanimously elected, is Mr. Edward Weston, of Newark, who, though born in England, has been so long with us, and of us, that we regard him as a first-class American in the best sense of the word. As an electrical engineer Mr. Weston is in the first rank. At present he stands practically without any affiliations, and is therefore in a position of independence rarely enjoyed by such prominent men in this country, it being generally the case that our leading inventors are throughout their careers actively engaged in, and associated with, large business enterprises. Mr. Weston has always had, I believe, a warm interest in the welfare of the institute, and may be counted upon for doing it good service during his tenure of office. It would not be surprising if he brought before it some of the many results obtained in his investigations at his fine laboratory at Newark. The institute during the past year has, as the secretary states, more than doubled its membership, having now over 320 members in all parts of the country and in all parts of the world. The increase is steadily maintained, and the accretions are of the best class. At the general meeting, held on Wednesday last at the house of the Civil Engineers, there was a very good muster of the members. The programme of the meeting has already appeared in your issue of May 25th.

While this has been going on in New York a very interesting meeting has been held in Philadelphia by the Franklin Institute, at which Mr. Emile Berliner, just referred to, read a Paper on his "Gramophone," which has already been illustrated in the electrical journals. This instrument, as will be remembered, practically etches the human voice, and reproduces speech by mechanical means. Mr. Berliner causes his recording stylus to move under the influence of sound waves, parallel with and barely touching the surface of a disc which is covered with some such material as lampblack. This record when made on the disc is fixed by varnishing, and can then be reproduced in a solid resisting material, such as metal, either by the mechanical process of engraving or by chemical deposition or by photo-engraving. The copy thus obtained can be multiplied to any desired degree. I have myself had the pleasure of listening to Mr. Berliner's gramophone, in which the record was made on a disc of plate glass, and the reproduction was excellent.

Among those who have grappled with the problems of aërial navigation is a Dr. De Bausset, whose ideas have been before the public for some time, and who proposes to use as his air-ship a huge metal cylinder, in which a perfect vacuum has been created, and to actuate all his machinery by electric-motor and storage battery. Dr. De Bausset has now succeeded in obtaining a favourable report on his air-ship from the Committee of Ventilation and Acoustics of the House of Representatives. The Committee recommend the appropriation of $150,000, and the use of the navy yard, provided that $75,000 of private capital is also put in. Should the scheme be carried out it will be watched with much interest. There is some scepticism as to the ability of the doctor's enormous cylinder to serve its purpose. If it is built up with thin plates

Digitized by Google

it may be unable to stand the pressure, and if made of thick plates it will be too heavy to lift.

A little while ago, I mentioned in this letter the fact that the Edison Company had made a movement to secure from the United States Circuit Court here a more favourable interpretation of the operation of that portion of the revised statutes which has been held to limit American patents by the term of corresponding patents taken out abroad. Judge Wallace, before whom the matter was heard, has, however, declined to upset the comity of the Courts in this matter, and the question must therefore await, I suppose, adjudication by the Supreme Court.

CORRESPONDENCE.

ELECTRIC OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the interesting Paper by Dr. Fleming in your issue of 11th May, on Electrical Oscillations, the graphic representa-

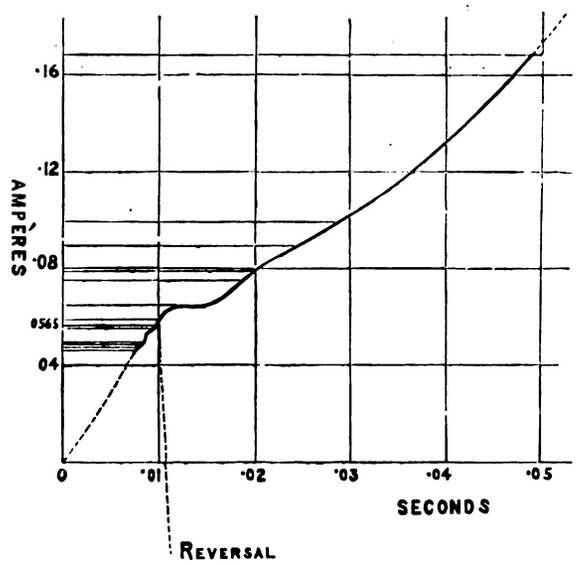

FIG. 1.

tion of the establishment and cessation of an electrical current in an inductive circuit—presumably an electro-magnetic one, as

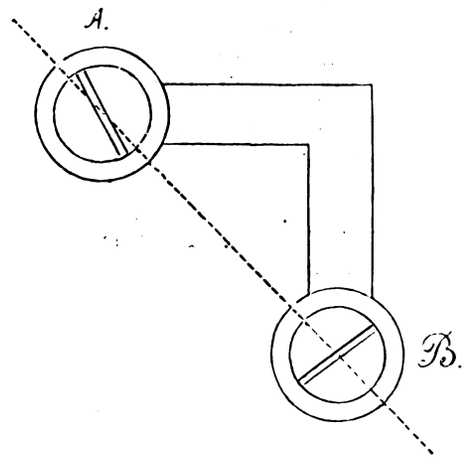

FIG. 2.

an induction coil is mentioned—does not agree with my observations on the curve in the magnets of type-printing telegraphs—at least as regards the cessation of the current.

In the case of the apparatus I refer to, the annexed diagram shows the increase of current, which is not uniform.

The cessation and complete reversal of the direction of the magnetism in the case of our working speed take place within the limits of the time shown by the thick and dotted line, or $\frac{1}{343}$th sec., the time line during which the battery is applied being $\frac{1}{100}$th sec., and the mean strength of current reached ·056 amperes, the maximum steady current in the circuit being 0 28 ampere.

It appears, therefore, that the phenomena vary somewhat with the arrangement employed; but in ordinary cases the cessation of the current is more abrupt than is shown in Dr. Fleming's diagram.

The experiment mentioned on page 8, paragraph 2, by which a discharge from Leyden jars takes the direct route through air instead of through the long wire connecting the two coatings, is what may be observed in case of all discharges which are of potential sufficient to jump through $\frac{1}{400}$th inch of air. For example, if two binding screws in such a circuit be connected together with a strap of brass ·002 of an inch thick, as in the full-sized drawing attached, a part of the discharge will, upon placing a straight conductor loosely across from A to B, jump through the imperfect connection, and cause a spark.

This spark increases enormously with any increase in deviation of the fixed connection from the straight path between the binding screws and independently of the resistance of the conductor. If a wire two inches long and less than $\frac{1}{350}$th ohm in resistance be made into a spiral, and placed in the circuit between the binding screws instead of the rectangular brass strip, then the sparks given off upon laying a straight iron conductor across the binding screws will be sufficient to mark the metal, and cause $\frac{3}{4}$in. of coruscation.—Yours, &c.,

17, Cornhill, E.C., May 29th, 1888. F. HIGGINS.

THE LEAMINGTON CENTRAL STATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the remarks which you made reflecting on ourselves in your issue of the 25th, in the first place we cannot refrain from telling you frankly that if you felt any of the "moral responsibility" about which you write you would not have made, on *ex parte* statements, the injurious comments in which you have indulged. There was ample time between the meeting of the Leamington Council and your publication of the 25th for you to have ascertained whether the statements to which you give currency were fair and impartial accounts of the position of affairs. Of course, as a matter of fact, they were nothing of the kind, and were not to be taken seriously as criticisms on electric lighting, but only as illustrations of personal pique or of trade rivalry or phases in the exigencies of local party warfare. Our installation at Leamington has now been running on a commercial basis for a little over three months. It will, to put it mildly, compare very favourably with any similar undertaking in Great Britain in a similar stage of its history. We have not lost a single customer since we commenced our supply, but, on the contrary, we are steadily increasing the business month by month, and enlarging and improving the plant. As to the Town Council and their street lighting, we are much more likely to give them notice than they are to give it to us. It is not we who would lose by this. Supplying the public lamps as we do at the cost of gas our contract can at the best only be described as selling twelve pence for a shilling. The Council, on the other hand, would lose the advantage of having two strings to its bow, and would be once more delivered up to the tender mercies of the Gas Company, who would re-establish their monopoly of public lighting.

We cannot accept your suggestion that we should give a history of our works; we are too busy to do it as a recreation, and if it were necessary to do anything to protect the reputation of our company a newspaper correspondence is not the method we should adopt.

We should, however, be very pleased to take you over our central station, and to show you our system in operation, and leave it to you to write from personal knowledge an impartial account of your experience.

We are certain if you accept this offer you will not again make the mistake of describing as a failure an installation

Digitized by Google

which Mr. Preece told our Mr. Hookham was unequalled in England.

Should you accept our offer and make arrangements with us to visit our works and see for yourself we leave it in your discretion to publish this letter or not; but if you decline our offer we have to request you to publish this letter and to give it the same prominence that you have given to the remarks of which we complain, and we should further request that you should not in future insert in your paper reports likely to injure our reputation or business, or make comments thereon through which we sustain injury, unless you have first satisfied yourself that such reports are true in fact, and that your comments are fair, reasonable, and justified by public interests.—Yours, &c.,

(For CHAMBERLAIN AND HOOKHAM, LIMITED.)
JOSHUA BROWN, Secretary.

Birmingham, May 29th, 1888.

[Our remarks on the above letter will be found in this week's "Editorial Notes."—ED. *E.*]

THE INVENTION OF THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me, in acknowledging your kind remarks on my letter on the above subject, to say, with regard to the patents of Mr. Edison and Dr. Siemens, that the thought of anticipation on the part of my father was suggested by one of Mr. Edison's specifications, No. 4,226, 1878, which contains this claim:—"The rod will expand in proportion to the heat of the coil, or in proportion to the heat developed by the passage of the current, and forms the principal feature of my invention." My father's device, as already described, was "based upon the heating and expansion of metals by the current to be regulated." Urquhart further adds, after mentioning "the self-same principle employed by Mr. Edison," "Dr. Siemens has constructed a regulator of a strip of platinum. The action is the same as that employed by Messrs. Staite and Edwards." Of the similarity or dissimilarity of these descriptions you will judge. May I suggest, with reference to your remarks, that in such a case as mine "the mischief is past remedy," that it would not be so if those gentlemen who are unconsciously using my father's improvements, and the public who are adopting them, felt that a claim existed, and were willing to respond to it?—Yours, &c. G. H. STAITE.

Sutton Cheney Vicarage, Hinckley, May 29th, 1888.

TAVENER'S COULOMB METER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The paragraph in the letter of your American correspondent, May 11th, giving Prof. Elihu Thomson the credit of being the first to utilise the heating effects of the current in conjunction with the differential thermometer, for the purpose of measuring and registering the quantity of current passing in a circuit, did not escape my notice. I should have called attention to the misstatement at once, without leaving the vindication of my claim to others, but felt that as you had so recently pointed out the novelty of my invention, which is substantially the same, it must be still fresh in the minds of your readers, who could not be misled by it. Since it has been stated that my invention is prior to Prof. Elihu Thomson's by more than four years there is only left me to say that had there been no patent to fix the priority of my claims, I could have brought ample testimony that for some time previously to 1884 I had been experimenting with the object of adapting the heating effects of the current in the construction of an electric meter, as it appeared to afford the only means of making a generally useful instrument applicable to both alternating and direct currents, which resulted in my adaptation of the tube with bulbs as the only solution of the difficulty of using the heating effects of the current in the way I have with a varying surrounding temperature and pressure.—Yours, &c.,

J. TAVENER.

South View, Basingstoke, May 29th, 1888.

ACCUMULATOR SWITCH-BOARD AND NEW METRE BRIDGE.

We illustrate herewith (Fig. 1) a switch-board made by the Woodhouse and Rawson Electric Supply Company (Limited), which is intended for a small installation with dynamo and accumulators. At the top is an ammeter of the Davies type and a voltmeter also of the Davies type. In the centre is an accumulator switch. On each side of centre is a two-way, G, switch, which are used for

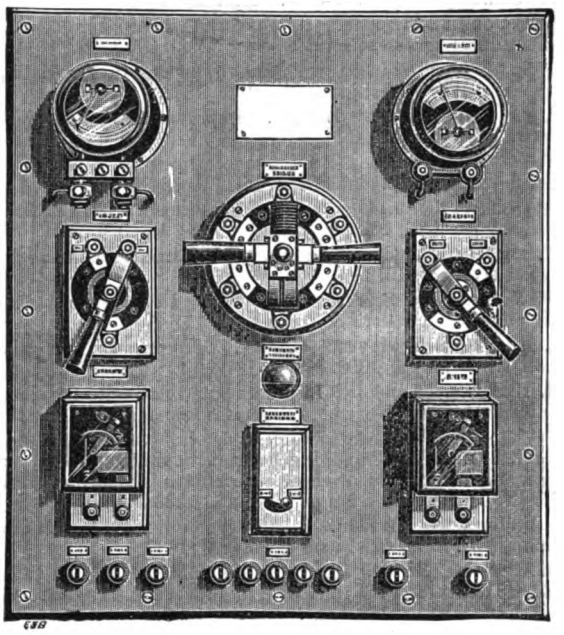

FIG. 1.

sending current from dynamo to line or accumulators, or from accumulators to line, or both at once. At the bottom are two magnetic cut-outs, one for dynamo and the other for accumulator circuits. There is also a voltmeter switch and fusible cut-out. The whole are mounted on slate base.

We also give an illustration (Fig. 2) of a portable form of metre bridge constructed by the same firm. The metre wire is wound on an ebonite cylinder, on which a thread is cut to receive it. Contact with the wire is made by a sliding piece fixed inside a collar, which is threaded inside to fit the screw thread in which the wire is wound. This collar is divided into millimetres and indicates the position of the point of contact, a small vertical scale giving the number of complete revolutions.

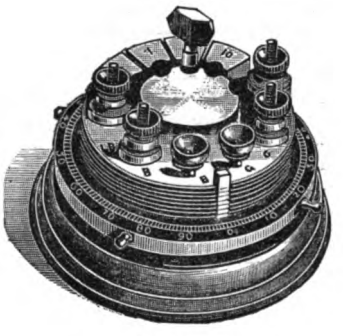

FIG. 2.

Standard coils are included in the instrument, and are connected to the brass blocks, shown at back, with a plug for putting them in or out of circuit. Two keys are placed in front, one for the battery and the other for the galvanometer circuit. Terminals are provided for galvanometer and line, battery and line, &c., which are exactly equivalent to those of an ordinary metre bridge, so that the whole arrangement is compact and portable, only occupying a space of 5½in. by 3½in. deep.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended May 25th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,366.

PATENT RECORD.

RECENT APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

6,237. A. MILLAR. Glasgow. Improvements in jars or cells for primary or secondary electric batteries. April 27, 1888.

6,270. H. C. JOBSON. London. Improvements in clips for attaching or fixing insulators to telegraph poles. April 27, 1888.

6,314. J. P. HALL. Manchester. Improvements in or relating to dynamo-electric machines. April 28, 1888.

6,322. P. R. DE F. D'HUMY. London. Improvements in galvanic batteries. April 28, 1888.

6,344. W. DAVIES. London. An improved means of conveying telegraph, telephone, and similar wires. April 28, 1888.

6,373. L. DILL. Berlin, Germany. Improvements in electric batteries. April 30, 1888.

6,382. W. MILLAR. London. An improved electric automatic delivery box. April 30, 1888.

6,390. W. MACKIE and S. SHARP. London. Improvements in electrical switches. April 30, 1888.

6,416. L. HOPPE and G. HOPPE. London. Improvements in galvanic batteries. May 1, 1888.

6,481. H. H. LAKE. London. Improvements relating to the electrical transmission of power and to apparatus therefor (N. Telsa, United States). May 1, 1888.

6,502. H. H. LAKE. London. Improvements relating to the generation and distribution of electric currents and to apparatus therefor (N. Telsa, United States). May 1, 1888.

6,578. J. Y. JOHNSON. London. Improvements in incandescent electric lamps (C. Philippart, France). May 2, 1888.

6,580. D. A. AIRD. London. Improvements in or connected with locks, catch latches, and the like, with means for releasing the bolt or catch by hand or electricity. May 2, 1888.

6,609. W. CHADBURN. Liverpool. Improvements connected with mechanical telegraphs for use in navigable vessels. May 3, 1888.

6,613. S. MILLER. London. Automatic resistance for electric-light circuits. May 3, 1888.

6,614. E. G. CRAVEN. London. Improvements in electrical illumination of clock dials and apparatus in connection therewith. May 3, 1888.

6,627. G. A. TABOURIN. London. A combined generator of electricity and electric lamp. May 3, 1888.

1,851A. J. Y. JOHNSON. London. A sound-conveying tube for telephones, graphophones, and like instruments (The Volta Graphophone Co., United States). February 7. Note—This application having been originally included in No, 1,851, dated February 7, 1888, takes, under Patents Rule 23, that date.

6,657. B. D. WILLIAMS. Bristol. Improvements in secondary batteries or electric accumulators. May 4, 1888.

6,740. J. T. ARMSTRONG and A. SERRAILLIER. London. An improved portable electric lamp. May 5, 1888.

6,834. A. P. CHATTOCK. Liverpool. An instrument for the measurement of the coefficients of electro-magnetic induction. May 8, 1888.

6,836. W. E. AYRTON, J. PERRY and D. COOK. London. An electrodynamic relay for constant or varying currents. May 8, 1888.

6,876. H. ARON. Liverpool. Improvements in apparatus for measuring electric currents. May 8, 1888.

6,889. O. FIRTH and E. W. CRABTREE. Bradford. Improvements in dynamos and motors. May 9, 1888.

6,893. E. C. WALKER. Darlington. Improvements in electro-magnetic and magneto electric generators. May 9, 1888.

6,907. M. IMMISCH. London. Improvements in storage batteries. May 9, 1888.

6,909. E. J. HOUGHTON. London. Apparatus for use with dynamo machines. May 9, 1888.

6,910. E. J. HOUGHTON. London. A system of electric lighting. May 9, 1888.

6,927. M. R. WARD. London. Improvements in electrically propelled vehicles and appliances connected therewith. May 9, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

May 5, 1888.

7,235. F. C. PHILLIPS and H. E. HARRISON. London. Improvements in the safety mechanism or cut-out of electric arc lamps or other electrical apparatus. May 18, 1887.

7,834. H. EDMUNDS. London. Improved means of controlling, transforming, regulating, synchronising, and registering electric currents. May 28, 1887.

8,214. W. P. THOMPSON. Liverpool. Improvements in telephone systems (E. Mauritius, Germany). June 8, 1887.

9,256. J. L. YULY and H. W. ANDREWS. London. Improvements in and apparatus for regulating the speed of dynamos employed on railway trains for lighting the same. June 29, 1887.

13,069. F. VAN RYSSELBERGHE. London. Improvements in or relating to harmonic telegraphy. September 27, 1887.

14,062. E. PULLAR. London. Improvements in automatic medical electrical apparatus. October 17, 1887.

15,537. R. W. PAUL. London. Improvements in electric switches. November 14, 1887.

17,047. F. KING. London. Improvements in secondary batteries. December 10, 1887.

137. J. C. PURTHNER. Vienna, Austria. Improvements in apparatus for producing induced electric currents. January 4, 1888.

3,075. A. W. SOUTHEY. London. An improved clutch for regulating feeding rods in electric arc lamps. February 29, 1888.

3,215. J. W. OLDROYD. London. Improvements in electric incandescent lamps. March 2, 1888.

3,235. G. MIOT. London. Improvements in multipolar dynamo-electric machines. March 2, 1888.

4,277. A. J. BOULT. London. Improvements in electro-mechanical movements (J. F. McLaughlin, United States). March 20, 1888.

4,929. W. GILLETT and G. HAZELTINE. London. Improvements in magneto-electric generators. April 3, 1888.

May 12, 1888.

6,400. J. R. SCHILLER and C. MEYER. London. Improvements in electro-magnetic apparatus for the automatic lighting and extinguishing of gas lamps. May 2, 1887.

7,189. W. H. AKESTER. London. Improvements in secondary batteries. May 17, 1887.

8,206. D. H. DAVIES and J. M. TOURTEL. London. Apparatus for effecting, by insertion of a coin, the production of electric light for a certain time. June 7, 1887.

8,495. A. M. CLARK. London. Improvements in electric lamps (C. Bertow, France). June 13, 1887.

9,598. J. A. TIMMIS. London. Improvements in electrical apparatus for working railway signals. June 7, 1887.

3,246. F. WALKER. London. Improved electrical lamp and projector, and method of applying same for maritime and other purposes. March 2, 1888.

3,303. H. H. LEIGH. London. Improved apparatus for registering the consumption of electric energy (J. L. Clerc, Paris). March 3, 1888.

LEGAL INTELLIGENCE.

The Brighton Electric Railway.

A special sitting of the Brighton County Court was held on Wednesday last, to hear a motion *in re* Magnus Volk, in which Mrs. Pryce Hamilton sought to set aside a decision of the Official Receiver (Mr. A. Mackintosh), rejecting a proof she had tendered for £1,539. 12s. 5d., for money lent and interest. The money had been advanced for the purposes of the Electric Railway, and the matter really raised the issue whether, under the terms on which Mrs. Hamilton lent the money, she was a partner in the concern, and therefore not entitled to move in competition with the other creditors. Mr. Rutherford, representing Messrs. Miller, Peal and Co., of Liverpool, appeared in support of the motion; Mr. Muir Mackenzie (instructed by Mr. Henry Prince) for the Official Receiver, and Mr. Treacher (representing Mr. J. K. Nye) for the debtor.

HIS HONOUR ultimately said the matter came before him in a peculiar manner. It was still undecided whether there should be a bankruptcy or a composition on certain terms, and the creditors were considering a proposal under which Mr. Volk's railway would be restored to him. If the property were re-vested in the debtor, the right of Mrs. Hamilton would remain the same under the agreement; and in the present state of affairs, no trustee having been appointed, he did not think he should determine the position of the parties. All that he thought it necessary for him to determine was whether Mrs. Hamilton had a right to prove as a creditor or not, and he thought not. If a creditor, she was only a creditor within the liabilities of Bovill's Act. He refused the application, with costs.

COMPANIES' MEETINGS & REPORTS

Oriental Telephone Company (Limited).

The adjourned eighth ordinary annual general meeting of this Company was held on the 25th May at the City Terminus Hotel, Cannon-street, under the presidency of Mr. B. St John Ackers.

The SECRETARY (Mr. Alex. B. Chalmers) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, I have first to regret the absence of our Chairman to-day. He is abroad, and the rest of the Directors have requested me to take the chair in the absence of Mr. Addison, who has also written to me to the same effect. I can only say personally that I regret that you have not your Chairman with you to-day. On the last occasion when we met it was the ordinary annual general meeting, and our legal adviser, Mr. Joseph Addison, of Linklaters, rose and told us that a case had been submitted to counsel, whose opinion had been received just before the meeting, and that it was advisable for us to adjourn the meeting for a month. The Chairman moved the adjournment, and in seconding it I used the following words:—"As you have heard from our legal adviser, we have every reason to believe that the dividend we were to recommend to you to-day will this day month be proposed, and, if the shareholders agree to it, declared; but until we have gone thoroughly into this question of back dividends and seen whether or not our capital has been reduced, as has been suggested, I think it would be very unwise to come to any decision. I therefore ask you to adjourn the meeting. But do not go away in the smallest degree despondent; we have had a very favourable year." My prediction as to the declaration of the dividend to-day has thus been fulfilled. I can only say that the Board very much appreciated the ready way in which the shareholders acceded to our request to adjourn the meeting, and I can only regret if anybody either here or outside, was led to take a despondent view of the affairs of the Company, because as I told you before, there was not the slightest reason for it; and I shall by-and-bye move, with your assent, that the dividend then proposed shall now be declared. You will see by the circular which has been sent out that since our last meeting the Directors have taken the opinion of their legal adviser—as well as that of the Company's auditor, and also that of an eminent accountant unconnected with the Company—and they are confirmed in their opinion that the assets are fully equal to the liabilities. We had gone over the question before, and you naturally will ask, as shareholders, why we had not altered the balance-sheet without being asked to do it from outside. There were several reasons that led us to desire to keep the balance-sheet as it was a little longer. To begin with, it is very undesirable to be frequently altering balance-sheets, and it was thought by the Board that there were certain circumstances likely to happen shortly that would form a very convenient time for making a thorough revision and alteration of the balance-sheet. Those points were the following:—First, we were anxious to get the Indian guarantees paid off before any alteration was made. Then we were also desirous of thoroughly determining, so far as we are able, whether the amounts which have been declared and paid as past dividends really were properly dividends or not, and that is a matter which is now receiving the very anxious consideration of the present Board. Then thirdly, there was the question of the vendors' shares. It seems to ordinary people who are not so much, perhaps, connected with these companies as those who are, if I may use the expression, professional directors, that it is very unfair that we should have in our balance-sheets to put down £75,000 of liabilities for vendors' shares, and that on the other side we should have to have assets from the first fully equal to that £75,000, and for this reason, that that £75,000 did not profess to carry dividends for many years to come, but only to receive dividends after 30 per cent. had been paid on the rest of the shares. Therefore, to ordinary minds, it would seem, provided you had on the opposite side made such provision that you had no reason to doubt that when the 30 per cent. had been paid on the other shares, then that the assets and liabilities would be equal to paying 20s. in the pound on the £75,000 of vendors' shares, that that would be a right and proper state of things. However, we are told there is no doubt whatever, and that there is no question as to legality or otherwise in this matter; the law says that you must have from the first the assets on the one side fully equal to your liabilities on the other side for vendors' shares. It is not my intention at the moment to say anything more about the vendors' shares, but later on, at the proper time, I desire to do so, in the hope that some plan may be found by which the present somewhat conflicting interest of vendors' and non-vendors' shares may be arranged amicably, so that in the future we may have an undivided interest, which would be very greatly for the benefit of the Company. I propose as shortly and as briefly as possible to go into the altered features of the balance-sheet. I may say at starting that the revenue and the profit and loss accounts are not altered. If any of you have the old balance-sheet which was sent out to the ordinary annual meeting, and will compare it with the present one you will find that the differences are as follows:—If you will take the first item on the asset side the first item as it stood before was £113,990. That has been written down by the sum of £42,990, now making £71,000. This old sum of £113,990 is the original sum, if I may so say, of the £115,000 which stood there from the commencement. If you remember, by the agreement made in the early history of the Company there was to have been a larger amount paid for different things—such as patent rights, goodwill, &c. That sum was, however, reduced to £115,000, and that, again, was written down by the sum of £1,010 taken out of the sale of the Hawaian Exchange. That exchange was sold out and out, and the amount was deducted, leaving £113,990, instead of £115,000. Besides that amount the late Board in no way reduced that sum, at which the goodwill and patent rights had stood from the first; and, as you have already heard, your present Board had not intended altering it until next year. However, it is now altered. You will find that the next item, that of expenditure on formation of exchanges in hand to date, is not altered. We believe that that sum fully represents our present property, and we have kept and are keeping in excellent repair and working order all the different exchanges. The total sum of those two items is, therefore, now £105,629 1s. 2d., instead of £148,619. 1s. 2d. If you go down a little further you see a very considerable change in the appearance of the balance-sheet. It was pointed out that it would be better to bring up the Deferred shares, and to value them altogether with the other shares in the subsidiary companies held by your Company, and not to put them down, as was done in previous balance-sheets, unvalued. It has also been suggested by the Company's auditor, who is appointed, as you know, by the Company, and not by the Board, that it would be well to have the value of the whole of these secureties brought out into one total instead of specifying the value of each item separately. That seemed to the Board a very wise suggestion, because in so many different subsidiary companies there may be ups and downs, and one of them may be more satisfactory this year and another more satisfactory next. It has, therefore, been thought better to make one total sum. Of course, we have the different amounts at which in the opinion of the Board these shares in subsidiary companies should be valued. The Deferred Indian shares have merged now that the guarantees have expired—that is to say, some have already merged, some are merging: and they will all have merged by the end of this year. There will, therefore, be no Deferred shares in connection with the Indian companies, and all the shares—the old Deferred shares and the Preferred—will rank for dividend. You will see, therefore, that

Digitized by Google

this old item of £45,760. 15s. 9d. has been written up by the sum of £43,355. 4s. 1d., making a total of £89,115. 19s. 10d. If you go to the bottom of the balance-sheet you find a total of £209,432. 10s. 9d., against £209,067. 6s. 8d.; or, in other words, after these figures have been carefully not only valued, but re-arranged, it is seen that the assets are, as the Directors said they were, amply sufficient to meet all the liabilities, and there is a small profit over of £365. 4s. 1d. You will see that telephone patents, goodwill, &c., have been decreased by £42,990, whereas the portions of the patents and goodwill which have been sold to subsidiary companies have increased by £43,355. 4s. 1d., leaving this balance of £365. 4s. 1d. If you look at the other side, one item will finish the whole alterations. You see sundry credit balances stood before at £1,874. 13s., and we have added the £365. 4s. 1d., increasing that item to £2,239. 17s. 1d., that being the excess of assets over liabilities. I think you will say that that is a very satisfactory state of things so far as the thorough soundness of this Company goes, and that it proves that your present Board at any rate have been justified in recommending to you a dividend of 2½ per cent., which they proposed at the last meeting, and are again going to propose for your acceptance to-day. There are one or two other points that it would be, perhaps, as well I should make a few remarks upon. These are the following:—It may be asked, "How have you arrived at the conclusion that the assets are worth a certain sum?" Well, at the amount at which we have valued them they pay us in dividend at the present time 6 per cent., and we think that a 6 per cent. steady dividend-paying property is worth par to us at any rate. It also might be asked why we do not propose to pay a higher dividend at the present time. Well, to begin with, if you carefully look into the accounts you will see that we have not got the cash in hand to do it. It is true that the profit and loss shows a balance of over £6,000, but there is a debt from the Egyptian Company of £6,287. It is hoped that that amount may be paid off during the year, but I would rather leave that matter to the Directors of the Egyptian Company than go into it myself from this chair to-day. But even supposing it were paid off, it would be very doubtful policy to spend all our spare funds in hand for dividend. I am one of those who believe that when we meet next year, the dividend will be sensibly increased from what it is this year—sensibly. At the same time, I think it would be very unwise in the present condition of the Company to spend all your money in hand in dividends. We have no reserve fund. There is no way at present of obtaining any extra amounts for working capital except to call on the shareholders—a proceeding which I do not think would be, at any rate, generally acceptable. Then I will read to you from the Articles of Association one paragraph, which touches upon the question of dividends. It is as follows:—"The Directors may, before recommending any dividend, set aside out of the net profits of the Company such sum as they think proper as a reserve fund to meet contingencies, or for equalising dividends, or for repairing, or maintaining, or extending the buildings or plant connected with the business of the Company, or any part thereof, and subject to these regulations, may from time to time apply the whole or any part of such fund for any purposes of the Company." That shows that there is full power to treat this in such manner as may be thought best. Your Company at the present time is earning a dividend which I think if it were paid in full would be considered decidedly satisfactory by the shareholders; and my great object in the remarks which I am now going to make is, if possible, to see whether we are not able, having shareholders with different interests at the present time, so to manage, as I said before, that we may have one interest, and if we had that one interest I am sure we should soon pay very handsome dividends in this Company. I have already referred to the question of the vendors' shares. You are aware, gentlemen, that the vendors' shares are 75,000, for which I do not say for one moment that an equivalent was not received, but at any rate for which not one penny was paid. Now, all the rest of the share capital is capital which at any rate has been paid for in hard cash. As you know, the vendors' shares are at the present time nominally £1 paid. The other shares have 11s. out of the £1 paid on them. Well, I have already alluded to the very grave doubt whether the previously declared dividends were or were not dividends at all; and touching on this question of the vendors' shares it would be very desirable either by means of the Board and the shareholders generally, or by a committee, or by any other means that might be considered to be the best, to see whether or not some arrangement could not be made (of course, something must be given on either side) by which the vendors' shares should be reduced in amount, the liability on the other shares wiped out, and the vendors' shares rank very soon for dividend. At the present time they cannot get anything until 30 per cent. has been paid upon the other shares. Now, 30 per cent., even supposing the previous dividends were real dividends, will take some very considerable time before it can be obtained; but supposing—to take the other view, and a probable view—that the back dividends were not dividends at all, then it means that 30 per cent. has to be paid from the present moment before anything can be received by the holders of the vendors' shares. The present Board, as a Board—which I think very fairly represents both sides of the question—hold, I believe, over 30,000 non-vendors' shares, and over 15,000 of the vendors' shares. It would not be difficult to pay larger dividends provided we had a working capital. It would be possible to get that working capital if we had calls on the unpaid amount of these shares; but that was tried some time ago, with the result, I think, that the shareholders got a 5 per cent. dividend, speaking roughly, and had to pay 10 per cent. in calls. I do not think they will be very desirous of following that plan again, and there is this to be said, that it is not altogether for the benefit of the vendors themselves that calls should be made on the other shares, because if the whole pound of flesh were exacted, and if the 9s. a share now unpaid were called up, it would mean £99,000 extra ranking as dividend, being a larger sum a great deal than the whole of the vendors' interest in this Company. I will not detain you by going into further details. They are more suitable for a committee or between Directors and the holders of the two different sets of shares than an occasion such as the present; but I have said enough, I hope, to show that there is on the part of the present Board, at any rate, an earnest desire to meet and consider the claims of all the shareholders of both kinds, that we believe that an arrangement could be made by which the holders of the vendors' shares would benefit quite as much as the other shareholders, and that if such an arrangement were carried out, it would be very greatly indeed for the benefit of this Company, for we should be a united body. We should then have by such an arrangement working capital, and be able to pay all fairly-earned amounts out in honest dividends year by year. Before I sit down there is one other point I would like to touch upon. In the last report—the report for the previous year—it was stated that the question of the Company's patent rights in Australasia has again occupied much of the Board's attention. This does not fall into the year 1887, which we are really considering to-day; but I thought it might interest the shareholders present to know that that long and weary litigation, as it was at one time feared it would be, and that long and weary negotiation, as it has been up to the present time, has at last ended, and that if we have not got as much as we think we ought to have got, we have at any rate made an arrangement such as will prevent any action being taken on one side or the other, and by which the rights of the Company are recognised over the whole of Australia, New Zealand, and Tasmania, and by which the Company will receive an annual amount in royalties. The one reason why we have not obtained all we ought to have obtained is that the Melbourne Exchange has been purchased by the Colonial Government. One of our great interests lay in that exchange. The Government have laid their hands on it, and, that being so, we have been advised that it would be extremely difficult for a private Company to get back anything, or to obtain anything from a Government, especially from the Government of one of the Colonies, where the laws are very strict.

I hope you will think that the Board have considered the interests of the Company in agreeing to an arrangement by which, subject to six months on either side, all ideas of litigation are to cease, by which our rights are acknowledged, and by which we receive a royalty in the different Colonies. I do not know that there is anything more to say, but if any shareholder wishes to ask any questions I shall be very glad to answer them. I now beg to move the adoption of this report and balance-sheet.

The Right Hon. G. CAVENDISH-BENTINCK, M.P.: I beg to second that.

Mr. W. S. CUFF said he did not take a despondent view of the Company's affairs, but a very hopeful one. He desired, however, to ask one question. They had learnt by the report that the dividend of the Egyptian Company had been brought into the accounts, that the revenues of the Indian companies were maintained, and that the exchanges worked by the Company all showed a profit. The question he wished to ask was, why, notwithstanding those three favourable facts, the profits were only £12 more than those of the previous year? He had no doubt that it could be explained. The idea of the Chairman as to a reorganisation of the capital was very desirable. He thought it would be very beneficial if they could get a small consultative committee of the shareholders representing both classes of the shareholders to act with the Board.

The CHAIRMAN: Perhaps if any other shareholder wishes to ask any question he will do so. I would like to reply altogether, as that would be the simpler way. No other shareholder rising to address the meeting, he continued: The answer to Mr. Cuff's remarks would seem to be that the progress is practically the same. There is only 1 per cent. more from the Egyptian Company than last year. We had 5 per cent. in the previous year, and we have now 6 per cent. I think we have had a fair return from India, but there has been rather a heavier loss on exchange last year. He then put the motion in the usual way, and declared it carried unanimously. Continuing, he said: The next resolution which I have the honour to propose is:—

"*That a dividend at the rate of 2½ per cent., free of income-tax, for the year ended 31st December, 1887, be declared on the paid-up capital of the Company, other than the vendors' shares.*"

Mr. G. B. FROST: Gentlemen, I have much pleasure in seconding this resolution. It is quite true that the dividend is a small one, but I am perfectly certain that it is the beginning of better things. I take a very hopeful view of the future of the Company, and when we come to remember that this day week will see the end of the Indian guarantees—that we have no such liability in the future—I am certain that it does not take a very profound prophet to predict the future prosperity of the Company. I have much pleasure in seconding the motion.

The CHAIRMAN put the resolution, and declared it carried unanimously.

On the motion of Mr. THOMAS LLOYD, seconded by Mr. HENRY GREWING, the Right Hon. G. A. F. Cavendish-Bentinck, M.P., was re-elected to his seat at the Board.

Mr. CAVENDISH-BENTINCK: I have to thank you for the honour you have done me in re electing me a Director of this Company. I was nominated to that post at the first almost without my consent being asked, but since I have been a member of the Board I have done my best to fulfil my duties, as I think the attendance book would show.

Mr. GREWING then proposed, and Mr. FROST seconded, the re-election of Mr. B. St. John Ackers; and the motion was unanimously agreed to.

The CHAIRMAN: I am much obliged to you for the honour you have done me in re-electing me. I have a very large stake in this Company, and it will be my very earnest endeavour, not only for my own interest but also for the interest of the shareholders, to bring it to a successful issue.

On the motion of Mr. CUFF, seconded by Mr. R. WRIGHT, Messrs. Deloitte, Dever, Griffiths and Co. were re-elected auditors to the Company for the current year.

Mr. CUFF then proposed a vote of thanks to the Chairman and Directors. The Chairman had placed the position of affairs before the shareholders in an excellent manner. He (Mr. Cuff) believed they had got prosperity before them, and he felt that it was due to the efforts of the Directors for the way in which they had managed the business.

The motion was seconded, and carried unanimously.

The CHAIRMAN: On behalf not only of the members of the Board present and myself, but also on behalf of our absent Chairman, who devotes a great deal of time to this Company, I beg to return you our hearty thanks. You have given us your confidence, and I hope that that confidence is not misplaced. I am sure that we have a bright future before this Company, and I hope that the next time we meet we may have a better dividend to propose.

The proceedings then terminated.

Hastings and St. Leonards-on-Sea Electric Light Company.

The following is the report of the Directors, submitted at the ordinary general meeting, held at Hastings on the 22nd May, 1888:—

The Directors present herewith their statement of accounts for the year ended 31st March, 1888.

The Company is now supplying 30 arc and 864 incandescent lamps, as against 30 arcs and 704 incandescent lamps last year, again showing an increasing business. The Directors have every reason to believe that by laying down mains in new directions and increasing the plant, the demand for supply of electric light will enormously increase. The principal hotels are now lighted by electricity, with very satisfactory results, and applications are now being made to substitute incandescent lighting for gas in places of worship and other business establishments.

On referring to the profit and loss account it will be seen that the gross profit for the year amounts to £558. 18s. 1d.; but from this must be deducted interest on overdraft at bankers and on debenture bonds issued to the amount of £1,000, thus leaving a balance of £314. 9s. 4d., out of which the Directors propose paying a dividend of £3 per cent. free of income-tax, amounting to £205. 10s., and carrying forward the balance to next year's account.

The suggestion of the Directors at the last annual meeting of the shareholders as to raising a sum of £5,000 by means of debenture bonds was not carried out, but a sufficient number of shareholders were found willing to take up bonds to the amount of £1,000, bearing interest at 5 per cent. per annum. The Company's bankers, Messrs. Beeching and Co., kindly agreed to reduce the rate of interest on overdraft to £5 per cent.

The revenue account shows that a sum of £166. 6s. 3d. has been charged to that account for repairs to boilers, including a new fire-box put in by Messrs. Robey and Co., of Lincoln.

Messrs. Reeves, Langham and Woodhams are the retiring Directors, and offer themselves for re-election.

The Auditors, Messrs. Hart Bros., Tibbets and Co., retire, and offer themselves for re-election.

W. H. ALLEN & CO., York Street Works, Lambeth, S.E.

MAKERS AND PATENTEES OF THE

"KAPP DYNAMO."

The only Dynamo that has the following combined advantages: Perfect Ventilation, Positive Driving, No Wasteful Internal Currents, No Heating, Self-Regulation, Slow Speed, and Good Workmanship.

Sir WILLIAM FORWOOD.
EDWARD LAWRENCE, Esq.
ERNEST NOEL, Esq.
Sir JOHN PENDER, K.C.M.G.
J. DENISON PENDER, Esq.
The Right Hon. LORD SUDELEY, P.C., F.R.S.
LEOPOLD SALOMONS, Esq.
JOHN C. SALT, Esq.
C. A. WHITMORE, Esq., M.P.

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 525.—Vol. XXI. FRIDAY, JUNE 8, 1888. Price 4d.

NOTES.

The discourse on "Influence Machines" delivered by Prof. Silvanus Thompson before the Society of Telegraph-Engineers and Electricians on Thursday evening is an admirable example of the employment of the methods of historical research in the field of science. The learned Doctor bids fair to make this field his own. The historical development of the Telephone, the Mercurial Air-Pump, and the Incandescent Lamp, have each been studied by Prof. Thompson in minute detail; but the subject of the present Paper will possess for many minds a still greater charm in that it lies remote from the province of commercial utilisation and the claims of rival patentees. Seeing, moreover, that the electricians of the last century, both in this country, in Germany, and in Italy, gave so much attention to the problem of accumulation, the Author may be considered fortunate in the selection of the present subject of his researches. But the richness of the mine must, of course, have added enormously to the labour of collecting and arranging the material—of which, indeed, only a very small portion was actually put before the Society on Thursday evening. Everyone must therefore feel the more gratified that Prof. Thompson has already met with a well-deserved reward—and, as he himself would no doubt say, an entirely adequate reward. The discovery of a hitherto unknown drawing of the influence machine devised in 1778 by Erasmus Darwin—a sketch, in all probability made by the inventor himself—is a success of which Prof. Thompson may feel justly proud. No treatise on static electricity ought henceforth to be considered complete without including this sketch and a reference to the recovery, after the oblivion of over a hundred years, of this the earliest attempt to design an influence machine. We trust that Prof. Thompson will continue to devote his leisure time to the history of scientific discovery, and that his researches will be as fruitful in the future as they have been in the past.

We commence this week the publication of a short series of Papers by Mr. G. de Tunzelmann on the so-called "Unipolar Induction" phenomena. We have arranged for these articles because we have good reason to believe that the questions involved will shortly assume a greater practical importance than is the case at present. The subject is one upon which a good deal of misapprehension—or at least difference of opinion—exists among practical men, as was evidenced by a prolonged discussion which took place in our columns last year. Since that date Prof. Edlund has added an elaborate theoretical Paper to his former investigations into these phenomena, and, though his theory is not generally accepted, his last Paper has given rise to a most interesting discussion of the whole subject among Continental physicists. Many of these phenomena are very little known or understood, and we imagine that several which will be discussed in Mr. de Tunzelmann's Papers will be new, and possibly even somewhat surprising, to the majority of our readers.

Lord Thurlow's Bill to amend the Electric Lighting Act of 1882 having now reached the Committee stage in the House of Commons, we may venture to anticipate that it will become law before the expiration of the present session. So far it has attracted very little attention in the Lower House, although its progress has been hampered by an inconsiderate proposal on the part of Sir George Campbell, and by the polite attention of the estimable Mr. Biggar, who took the earliest opportunity to move to report progress. Sir George Campbell's proposal practically amounted to the introduction of free competition in electric lighting. It is not necessary at the present juncture to discuss the general question thus raised, since it is sufficient to reply with Sir Michael Hicks-Beach that the amendment is opposed to the whole scope and purpose of the Bill. It is a great pity that private members should delay the progress of a measure which they evidently have not taken the trouble to understand by proposals of an impracticable character.

The only local inquiry under the existing Electric Lighting Act which the Local Government Board has yet had occasion to hold took place at Bradford last week, and is fully reported in our present issue. When the good people of Bradford learnt that nothing could be done without the official sanction of the Board, and that this would not be granted until an inquiry had been held, some rather strong language was indulged in. But the issue cannot be said to have justified these apprehensions, however well founded they may have been. The inquiry has been held within a very few weeks of the notice being given, and after hearing from the Town Clerk the history of the scheme, the inspector (Major Tulloch) promptly intimated that no objection would be raised on his part to the completion of the undertaking. The Corporation are now applying for powers to raise an additional sum of £5,000 (making £25,000 in all) to cover the cost of the preliminary installation. With Dr. Hopkinson as consulting electrician and Mr. Shoolbred as electrical engineer, the Corporation *ought* to experience

Digitized by Google

no serious difficulty in carrying the undertaking to a completely successful issue.

It is, perhaps, a fortunate circumstance that a very excellent example of central station lighting is already in existence at Bradford (for full description of which see *The Electrician*, Jan. 6, 1888, p. 204). The efforts of Messrs. Schmidt, Douglas and Co., although on a much smaller scale than that now contemplated by the Corporation, have already educated the people of Bradford up to the idea of what central station lighting ought to be, and it will be impossible for the Corporation to offer them anything of a less satisfactory character. We thus possess an additional guarantee that no effort will be spared to secure the best possible results. It is only fair to add that Messrs. Schmidt, Douglas and Co. have carried out their work under exceptionally favourable circumstances as regards the area of distribution, and in particular that they have not had to face the problem of underground mains.

On the occasion of the *conversazione* given by the Royal Society on Wednesday evening last, it must be admitted that the devotees of botany, zoology and mineralogy were principally to the fore. Fresh water jelly fish, nests of living ants, and flies sucking sugar under miscroscopes attracted a large share of attention. But electricity cannot be altogether excluded from the field of zoology, a fact which was exemplified by the presence of a very fine specimen of the electric eel *(Gymnotus electricus)*. During the evening several of the guests were induced to test the electrical condition of the *Gymnotus*, with results of an amusing character to the onlookers. The General Post Office contributed a duplicate set of the Delany Sextuplex Telegraph, an instrument which has now been brought to great perfection. Robertson's Writing Telegraph was also again *en évidence*. Profs. Ayrton and Perry showed various novel applications of their magnifying springs, including a vacuum and pressure gauge, an apparatus for measuring the coefficient of expansion by heat, a micrometer, a thermometer, and a portable voltmeter. Perhaps the most interesting of these is the micrometer, which is capable of indicating the one twenty-thousandth of an inch. This instrument was made by Mr. C. Bourne (of the Central Institute). The spring itself has a diameter of only one or two thousandths of an inch, and in appearance it can scarcely be distinguished from a thread of cotton. By permission of Mr. D'Oyly Carte, the United Telephone Company laid on telephonic communication with the Savoy Theatre, and the music of the "Pirates of Penzance" was transmitted with much success. In another room Mr. C. V. Boys exhibited the remarkable experiments with soap bubbles which he has recently devised, and which so beautifully illustrate the laws of surface tension in liquids. The elementary laws of static electricity were also strikingly exemplified in the following way:—Two bubbles resting one against the other are shown to coalesce instantly when the most feebly electrified body is brought near, but when one bubble is blown inside another (a feat which Mr. Boys performs with the greatest ease and certainty) the inner bubble is completely protected by the outer, even from comparatively powerful electrical influence, and so the bubbles remain separate. On the ground floor a series of lantern demonstrations were given by Prof. Ray Lankester, Mr. W. Gardiner and Mr. J. Norman Lockyer, in which the electric lantern supplied by Messrs. Drake and Gorham was brought into use. We need scarcely add, in conclusion, that the *conversazione* was a brilliant success in every sense of the word.

The shareholders of the Swan United Electric Light Company seemed to be quite satisfied with the terms of the provisional agreement with the Paris Edison Company which were laid before them on Tuesday last. By this agreement it is provided that the share capital of the joint company is to be 2,000,000fr., of which 1,000,000fr. will represent in fully-paid shares the value of the combined businesses as going concerns. These shares will be divided between the Edison and Swan Companies in the proportion of three to two respectively. The remaining 1,000,000fr. is to be subscribed in cash by the two companies in the same proportion. The Swan Company has therefore to raise £16,000, and the Edison Company £24,000. The difficulty of arriving at a working arrangement was considerably enhanced by the fact that while the English Company are the sole owners of the Swan patents in Europe, the French Company are paying to Edison a royalty of 20 centimes for each lamp manufactured. Moreover, by the terms of their agreement the royalty was to continue so long as the company existed. A reasonable compromise has, however, been arrived at. The payment of the royalty will now terminate with the expiration of the patents in 1894, but meanwhile it will be paid upon the whole of the new company's manufacture. The agreement does not at present extend to Germany, where litigation has already been in progress between the two companies for some considerable time; but we take it that a compromise is certain to be arrived at in this quarter also, the situation having become too anomalous to last. Meanwhile, it is interesting to know that Messrs. Siemens and Halske are paying the Edison Company a royalty of 37½ centimes upon each lamp manufactured by them. It need hardly be said that the amalgamation is likely to bode no good to those makers of lamps upon the Continent who have hitherto refused to recognise the claims of either of the quondam rivals.

Owing to a sudden strike of the stokers at the Grosvenor Gallery on Sunday evening last a number of buildings in the West End were deprived of light. The Secretary of the Company states that the men left work because a gratuitous meal of roast beef, etc., was served to them cold instead of hot. Anything more insufferable can scarcely be imagined. We most sincerely trust that the London Electric Supply Corporation will find themselves in a position to prosecute the men, and that they may meet with exemplary punishment. When the stokers of the London Gas Company struck work not many years ago—or, at least, threatened to do so—the law was found to be powerful enough to prevent the carrying out of their mischievous designs. It would be an intolerable state of things if electric light enterprise were left at the mercy of men of the stamp of the ex-stokers of the Grosvenor Gallery

Digitized by Google

The "Elektrotechnische Zeitschrift."—The *Elektrotechnische Zeitschrift*, which has hitherto appeared monthly, is now being published every fortnight.

Exeter.—The Exeter Electric Light Company have commenced operations at Trew's Weir, on the River Exe, where the central station will be established.

The Use of Electric Light for Sea Fishing.—Some German sea fishermen are making experiments with the electric light for night fishing. So far the results are said to have been highly satisfactory.

Elster's Bunsen Photometer.—The Imperial Technical Society of Russia have decided, on the report of the Expert Committee of the Petroleum and Lighting Exhibition, recently held in St. Petersburg, to award to Herr S. Elster, of Berlin, the Society's medal for his Bunsen photometer, which they have found to be specially valuable in practical working.

Spanish Tender for Telegraphic Cable.—The Madrid *Gazette* has published a notification from the Posts and Telegraphs Department, inviting tenders for the construction and laying of a submarine telegraph cable between Javéa and the Island of Iviza (one of the Balearic Isles). Tenders are invited for June 27th. The maximum estimate is 300,000 pesetas—say £12,000.

Telegraphy Gratis.—Guadalajara, the second town in Mexico, has just been celebrating the opening of the railway between it and the capital. The Local Telegraph Company to mark the event permitted the free use of its wires to all comers. Up to noon this had resulted in the despatch of 1,236 message. As a local paper says, this is certainly "doing the thing handsome."

Alexandria.—The Ministerial Council of Alexandria have approved of the project for lighting the city by the Edison Electric Lighting Company, but only on condition that the contractor will hold himself responsible for all damages that the Egyptian Government might be called upon to pay to the Gas Company, should the latter deem it advisable to take legal proceedings against them.

"Electrical Plant."—Commenting on its first anniversary, our contemporary *Electrical Plant* expresses itself entirely satisfied with the support it has received, which it regards as evidence of a rapidly increasing interest in electrical subjects treated from a popular standpoint, as well as of a growing demand for electrical plant. We trust that these anticipations may be realised.

The Copper Market.—According to Messrs. Merton and Co.'s copper statistics the deliveries in France and England had slightly increased this month, being 6,044 tons, compared with 5,877 tons in April and 4,489 tons in March. In the month of May, 1887, the deliveries were as much as 10,065 tons. On Wednesday there was a marked fall in copper shares, which continued yesterday, but prices of metal are still maintained.

The Van Rysselberghe System in Holland.—The *Journal de Gand* says that the trial of the Van Rysselberghe system, commenced some two years ago by the Dutch Government, has yielded unfavourable results. The authorities are going to abandon the system of simultaneous telegraphy and telephony, and have granted a concession to the Bell Company. Amsterdam and Rotterdam are to be united by a special telephone wire.

New Books.—Messrs. Macmillan and Co. will shortly publish a work on "The Theory and Practice of Absolute Measurements in Electricity and Magnetism," by Professor A. Gray, in two volumes. The first volume is just ready. It contains a sketch of the theory of electrostatics and flow of electricity, chapters on units, general physical measurements, electrometers comparison of capacities, &c. The second volume, dealing with magnetic theory, electric energy, etc, will follow soon.

Electricity in the Spanish Navy.—Major Cabanyes, of the Spanish army, is building a submarine torpedo boat, driven by electricity. The plant consists of a 60 horse-power motor, by Brown, of Oerlikon, and a battery of 60 accumulators. These accumulators are on a new pattern, and profound secrecy is maintained as to their construction. A very high capacity is claimed for them, and some trials recently made before the Spanish Government authorities gave great satisfaction.

Huddersfield.—At a meeting of the Huddersfield Chamber of Commerce, held a few days since, Mr. Crosland drew the attention of the council to the steps which are being taken in Bradford to light the town with electricity, and asked whether it would not be as well to suggest to the Town Council that they should take similar steps in Huddersfield.—Mr. Walker thought this matter was clearly beyond their province, and, after a desultory conversation, the subject was allowed to drop.

Bohemia.—For some little time the town of Neuhaus in Bohemia has possessed a central lighting station erected by Count Czernin, the chief landowner in the neighbourhood. The municipal authorities have signed a 20 years' contract for 85 16 candle-power incandescent lamps for street lighting purposes, while 365 lamps are used by private consumers, the demand in this direction being greatly on the increase. The plant comprises two dynamos driven by a turbine, and 1,000 accumulator cells.

The Lighting of the Prudential Assurance Company's Offices.—Messrs. Drake and Gorham have recently received instructions to put down a third engine and fourth boiler, as well as additional dynamo power, at the Prudential Assurance Company's offices in Holborn. The dynamos will be of Messrs. Crompton's make, as are the machines already in use. The accumulator arrangements are being modified throughout, in accordance with recent practice, and 264 of Messrs. Drake and Gorham's cells will be used in conjunction with the new plant. The total number of lamps will amount to 2,300.

Telegraphs in the Highlands.—The Telegraphs of the Highland Railway Company are being rapidly put in very substantial order on the inverted V principle. A fine specimen of a telegraph line, says *Engineering*, has recently been constructed between Inverness and Culloden, under the superintendence of Mr. Gilbert. The system is an excellent one, and the mode of construction appears to be specially suited for the country through which the Highland line passes. It has successfully withstood the severe gales and snowstorms of the past winter at such exposed points as Dava and Dalnaspidal—communication on either the Government or railway wires having in no way been interrupted.

The Electrification of Vapour.—Prof. J. L. Soret, of Geneva, has devised a pretty experiment showing the effect of electricity on collected dust and condensing vapours. He places in a darkened room a platinum crucible containing water, which is supported on a metallic stand connected with one pole of an induction machine. Above the crucible is placed a platinum point connected with the other pole. The water is caused to boil by the use of a Bunsen burner, and the whole is strongly illuminated by the beam of a powerful electric lamp. When the induction machine is not being worked the water vapour rises and is condensed in the ordi-

Digitized by Google

nary way, but on setting the machine at work and lowering the point near the surface of the liquid no vapour appears, though the water may be boiling briskly.

The Schmelzer Carbon Factory.—A correspondent writes as follows:—One of the most important carbon factories is Mr. Ch. Schmelzer's at Nuremburg, established in 1884. Since its commencement the undertaking has been remarkably prosperous, and at present about 75 workpeople are employed. After many costly experiments, Mr. Schmelzer has succeeded in constructing most efficient pressing machines, especially hydraulic pressing machines, working with a normal pressure of 600 atmospheres, and the machines now in operation are capable of producing 25,000 meters of carbon-rods per day. Two generators furnish the gas for two furnaces, which comprise about 30 cubic metres available space in 40 compartments. The factory is lighted by 20 arc lamps, fed by a Schuckert dynamo.

Long-Distance Telephony in Sweden.—A correspondent writes as follows:—"The Swedish Government has commissioned the State Telegraphs to build a telephone line between Stockholm and Gothenburg, *vid* Orebro and Mariestad. The cost of the present line is put at 420kr. per kilometre, and as the line is 530 kilometres long, the total cost will be 222,600kr. This calculation is based upon a double line of copper wire of at least 3 millimetres diameter, and a single copper line will also be erected on the same poles, principally for use between intermediate stations. The fact of the Swedish Government going in for the Stockholm-Gothenburg line itself is of course synonymous with a refusal of the Stockholm General Telegraph Company's application for permission to erect a similar line, although the decree in question does not say so."

The Phonozenograph.—The Duc de Feltre has designed an instrument, which he calls a phonozenograph, intended to indicate the direction of any distant sound. A microphonic plate of peculiar construction is fixed in a vertical plane, and is in circuit with a battery and a telephone receiver, or a Deprez-D'Arsonval galvanometer and a Wheatstone bridge. The microphone is more or less affected by a distant sound, according to the angle that it makes with the source. By moving the plate about until the maximum effect is obtained the observer is enabled to exactly locate the direction of the sound. The indications of the telephone receiver are absolutely accurate, but those afforded by the galvanometer are less so, and this latter arrangement will require great modification of the microphonic plate before it can be said to be of a practical nature. This instrument may possibly prove of use at sea in preventing collisions in foggy weather.

The Telephone Market.—The monthly circular of a firm of stockbrokers which devotes special attention to the telephones says:—"Telephones have been a quiet market, and prices close flat. The negotiations for the amalgamation of the various interests hang fire. The radical vice which has characterised all the operations of the United Telephone Company since its formation, namely, endless procrastination and discussion in place of action, is no doubt the cause. The shareholders of this company having received good dividends seem quite content to remain ignorant of, or to ignore, the shortcomings of their directors. But for the happy accident that subsidiary companies were formed, whereby the management in certain districts was transferred to abler hands, the United Company's dividends would have been small. The company, in fact, is to-day successful, not owing to the exertions of its management, but really in spite of the fact that its best interests have been neglected, and its most important field of operations left practically unworked."

Electric Traction in Australia.—A recent number of the *Melbourne Age* contains the following telegram:—"It is considered likely that the Sandhurst and Eaglehawk councils will very shortly decide upon the construction of tramways upon the electric-motor principle. The councils, as a result of their inquiries, seem pretty well convinced as to the advantages of this system. A letter has been received from Messrs. Booth, Ellson and Co., the agents for an electric system, offering to form a syndicate to construct and work the tramways. They make a preliminary offer of £100 per annum for the right, and one-third of the profits over 8 per cent. A conference on the subject with the firm will be held on Monday." Sandhurst is one of the most important towns in the immediate neighbourhood of Melbourne, and any successful scheme introduced there is likely to meet with rapid extension. The same paper contains a leading article in which the advantages of electric traction are spoken of with the greatest enthusiasm. We trust that Messrs. Booth, Ellson and Co. will succeed in their efforts.

Capital Punishment by Electricity.—The Governor of the State of New York has signed the Bill presented by the Legislature, which substitutes death by electricity for hanging as the mode of capital punishment. The new law originated with the following recommendation by the Governor in 1885:—"The present mode of executing criminals, by hanging, has come down to us from the dark ages, and it may well be questioned whether the science of the present day cannot provide means for taking the lives of such as are condemned to die in a less barbarous manner. I commend this suggestion to the consideration of the Legislature." In 1886 a Commission was appointed by the Legislature to investigate and report upon the most humane and practical method of carrying into effect the sentence of death in capital cases, and the present change is the final outcome of the report of this Commission. The new law will come into operation in January, 1889. We have already expressed our own views on the subject, and trust it will be a very long time before electricity is called upon to do the hangman's work in this country.

Safety Signal Apparatus by Siemens and Halske.—An interesting description has lately been given by Herr Frischen, at the Polytechnic Society in Berlin, of a signalling and stop-motion apparatus for preventing accidents with steam machinery in large factories, constructed by Messrs. Siemens and Halske. Since in Germany the law has insisted that arrangements are to be made in factories for stopping machinery as quickly as possible at will, and that a clear signal is to be given every time before applying the steam power, considerable attention has been devoted by engineers to ascertaining how these requirements may best be fulfilled. Messrs. Siemens and Halske have introduced an electrical apparatus which is entirely automatic. The arrangement is extremely simple. An electric bell circuit is taken through all the rooms in the factory, including the engine room. The bells are rung by clockwork mechanism, which is held in check by a current which is kept continuously in the circuit. Every room is provided with a switch for breaking the circuit, which, of course, sets all the bells ringing. The starting or stopping of the engine is also made to do the same thing automatically.

The Vagaries of Lightning.—In *The Times* of Saturday last Mr. C. Tomlinson offers the following explanation of one of the many vagaries of lightning. He says:—"If it be granted that animals are more liable to the attacks of lightning than human

Digitized by Google

beings, have we any explanation of the fact, if fact it be? When Snow Harris was planning his system of lightning conductors for the then recently completed Houses of Parliament, he explained to me the necessity of strongly protecting the ventilating shaft of the House of Commons. As a coke fire is usually kept burning in this shaft for the purpose of maintaining a ventilating force, a column of warm rarefied air ascends from this shaft to a considerable height, and would probably act as a line of least resistance, and so determine the course of a stroke of lightning. So, also, a flock of sheep huddled together during a storm would produce a similar column of warm rarefied air. Thus to mention one case out of a thousand, on the 17th of August, 1858, at Sacco, in the kingdom of Naples, out of a flock of 140 sheep the lightning killed 120; but the shepherd was not touched, and the shepherd boy escaped; but this puzzling fact is added—a kid which the boy held in his arms was killed. But for this, I should be disposed, to explain the recent case mentioned by Mr. Dudgeon on the above ground; the horses just taken from the plough were very warm, and sent up a steamy, rarefied air which acted as a line of least resistance to the disruptive discharge. The man probably did not share in this rarefied air, and so escaped from the lightning, only to be injured by the fall of the horse."

Fatal Accidents to Electric Light Linemen in Halifax, N.S.—The papers on this subject kindly sent us by Captain H E. Rawson, R.E., but which failed to come to hand, have been supplied us by Mr. Stepney Rawson, and we are now able to supplement our account of last week. From Captain Rawson's exhaustive evidence before the coroner's jury, which was fully corroborated by independent witnesses, it seems plain that the two fatal accidents which took place within forty-eight hours were entirely due to preventible causes. The lamps in use are Ball arc lamps, one terminal of which is insulated from the frame, while the other is part and parcel of it. The leads were of the wretched "underwriter's" type, and only 9in. apart. The pole at which the accident took place was the third from the dynamo, and owing to its position the whole of the wires leading to and from it are stretched parallel to one another. The circuit contained 75 lamps in series. On examining the lamp, Captain Rawson found that the + pole was in connection with the frame through the charred coils of the lifting magnet, and also (if they were at all damp) through the four strands of small manila rope fixing the carbon frame to the standards on either side. The wires were bare in several places, and in addition Captain Rawson found that a very small amount of moisture destroyed their insulation. In order to get at the lamp, the man must have sat upon the return wire, and on touching the lamp frame, got the full current through his body. The jury returned a verdict to the effect that Crocker's death was the result of accident, censuring the Chandler Electric Light Company for not taking precautions to prevent further fatalities on the lamp on which Webber had lost his life the day before, and making a number of recommendations.

The Electric Lighting of Spanish Theatres.—It appears that difficulties have arisen in carrying out the recent Royal decree issued by the Minister of the Interior, ordering the compulsory lighting of Spanish theatres by electricity. The Comedy Theatre of Madrid recently put up an installation and introduced the electric light, but objection was taken by an inhabitant living in the vicinity on the ground, it is asserted, that the noise caused by the motor was a public nuisance. The various accounts in the different Spanish papers are somewhat contradictory; but it would appear that on the objection being made the matter was laid before the civil authorities, and before the Theatrical Board in Madrid, both of which bodies, after examining the matter, reported the installation to have been erected in complete conformity with the regulations laid down in the Royal decree referred to, and this decision was given after the installation had been inspected by the municipal architect. It would appear, however, that the aggrieved ratepayer has taken the matter into the courts, and that the judge has forbidden the Comedy Theatre to use the electric light, and has placed a man in charge of the motor to see that his instructions are carried out. The lighting of the theatre with the electric light has therefore been suspended, and, as the theatre is not supplied with gas, the managers have had to resort to candles. The Madrid paper, *El Imparcial*, in calling attention to the subject, refuses to question the right of the judicial decision, but asks how can the exigencies of the Government authorities be harmonised with the decision of the Courts? And further, in what position will the companies be in September next, by which date the use of the electric light in theatres will be compulsory. It is to be hoped, in the interests of the electric companies and theatre goers alike in Madrid that the views of the authorities in interpreting the conditions of the Royal decree and the decisions of the Court should be settled without delay, especially in view of the compulsory nature of the Government requirements in this matter.

The Australian Association for the Advancement of Science. In November, 1886, chiefly owing to the exertions of Prof. Liversidge, a preliminary meeting of delegates representing nearly all the scientific and learned societies throughout the Australasian colonies took place in Sydney, the object of the meeting being the formation of an association on the same lines as the British Association for the Advancement of Science. The outcome was the formation of the Australasian Association for the Advancement of Science. It was also decided that the election of officers should be held in Sydney, in March, 1888, and that the first general meeting of the association should take place in Sydney during the first week in September, 1888, it being considered fitting that the association should be publicly inaugurated during the centennial year. A meeting of the local council was held on the 7th of March, and the following gentlemen were appointed:—Mr. H. C. Russell, B.A., F.R.S., president; Prof. Liversidge, M.A., F.R.S., and Dr. George Bennett, F.L.S., honorary secretaries; Sir Edward Strickland, K.C.B., honorary treasurer. The objects of the association are:—To give a stronger impulse and a more systematic direction to scientific inquiry; to promote the intercourse of those who cultivate science in different parts of the British Empire with one another and with foreign philosophers; to obtain a more general attention to the objects of science, and a removal of any disadvantages of a public kind which impede its progress. The rules of the association are practically the same as those of the British Association. As in the case of the British Association, a local committee is to be appointed in the place of meeting, to make arrangements for the reception and entertainment of the visitors, and to make preparations for the business of the general meetings. Sectional committees are to be appointed for the following subjects:—Section A, astronomy, mathematics, physics, and mechanics; section B, chemistry and mineralogy; section C, geology and palæontology; section D, biology; section E, geography; section F, economic and social science and statistics; section G, anthropology; section H, medical and sanitary science; section I, literature and the fine arts; section J, architecture and

Digitized by Google

engineering. It will be seen that the Australasian Association proposes to cover a rather wider ground than its prototype, as it will embrace literature and art as well as science.

The Institution of Civil Engineers.—The annual general meeting—to receive and deliberate upon the report of the Council on the state of the institution, with the annual statement of the accounts, and to elect the council and officers for the ensuing year—was held on Tuesday, the 29th of May, Mr. George B. Bruce, president, in the chair. The report stated that during the twelve months ended the 31st of March, 1888, there had been an addition to the roll of 49 members and of 183 associate members, the number of non-corporate associates being reduced by 23. The increase had been 4·6 per cent. per annum, as compared with 4·19 per cent. for the previous twelve months. The students had increased by 25. At the date named there were on the books 1,617 members, 2,458 associate members, 461 associates, 20 honorary members, and 974 students—together 5,530. The receipts on account of income during the twelve months under review were £16,071. 12s. 2d.; on account of capital, £4,248. 11s. 2d.; and from trust funds, £433. 15s. 1d. The general expenditure had amounted to £13,956. 10s. 10d., of which more than one moiety constituted the cost of the publications. A sum of £6,476. 18s. 9d. had been invested in the purchase of £5,000 London and North-Western Railway Four per Cent. Debenture Stock, and the outlay on account of trust funds amounted to £476. 6s. 11d. These figures constituted the ordinary receipts and disbursements. Owing, however, to the purchase of No. 24, Great George-street, it had been necessary to sell railway debenture stocks of the nominal value of £9,000, and to transfer from the yearly receipts a sum of £4,617. 11s. 3d., to meet this outlay. The Papers read at the ordinary meetings had been of more than usual interest, and had given rise to animated discussions and to much correspondence. For some of the Papers the Council had awarded Medals and Premiums to Messrs. R. A. Hadfield, P. W. Willans, Dr. Edward Hopkinson, Messrs. E. B. Ellington, Josiah Pierce, jun., Sir Bradford Leslie, K.C.I.E.; and the Manby Premium to the late Mr. Hamilton Goodall. For Papers printed in the *Proceedings* without being discussed a Watt Medal and a Telford Premium had been awarded to Prof. Dwelshauvers-Déry, and Telford Premiums to Messrs. W. M. Thompson, J. W. Wyatt, and D. Drummond. Advantage had been taken of the increased accommodation to hold exhibitions of models, appliances, instruments, and specimens in connection with some of the subjects which came under discussion, viz.:—"Accidents in Mines," "Manganese Steel," and the "Use of the Plane-Table in Topographical Surveying." The success of these exhibitions had formed a most acceptable feature of the Tuesday evening meetings of last session, and it was hoped that they might be repeated and further developed as opportunity occurred. The ballot for council resulted in the election of Mr. G. B. Bruce as president; of Sir John Coode, Mr. G. Berkley, Mr. H. Hayter, and Mr. A. Giles, M.P., as vice-presidents; and of Mr. W. Anderson, Mr. B. Baker, Mr. J. W. Barry, Sir Henry Bessemer, F.R.S.; Mr. E. A. Cowper, Sir James N. Douglass, F.R.S.; Sir Douglas Fox, Mr. C. Hawksley, Mr. J. Mansergh, Mr. W. H. Preece, F.R.S.; Sir Robert Rawlinson, K.C.B.; Sir E. J. Reed, K.C.B., F.R.S., M.P.; Mr. W. Shelford, Mr. F. C. Stileman, and Sir William Thomson, F.R.S., as other members of the council. The session was then adjourned until the second Tuesday in November, at 8 p.m.

The Eastbourne Central Station: Visit of the Cheltenham Town Council.—A few days ago the members of the Electric Lighting Committee of the Cheltenham Town Council paid a visit to Eastbourne to see the electric light in operation there, and to inspect the plant laid down for its supply. The following report from the *Cheltenham Mercury* will be of interest: "The consideration which chiefly guided the committee to the selection of Eastbourne was that the installation in that town had been established under conditions as dissimilar from those existing at Taunton as any they could find, and offered an opportunity of comparing two fairly successful examples of different systems of lighting. The installation at Eastbourne was originally made about six years ago by the Anglo-American Brush Electric Light Corporation, but it has for some time passed into the hands of the Eastbourne Electric Lighting Company, and by this company extensive alterations and improvements have been carried out. The works are in the centre of the town, and are located in premises much more commodious than those at Taunton. The machinery also is more powerful, the dynamos being driven by a fine engine of 200 horse-power. In addition to the Brush dynamos originally used, three of newer construction have lately been laid down, and the machinery appears to now be equal to any demands likely to be made upon it for some time to come. Both arc and incandescent lights are maintained, the former for street lighting and the latter for internal illumination. Of public arc lamps there are 21, confined to the sea-front or parades, and extending about 2,000 yards. Of incandescent lights about 1,500 are supplied, and the public buildings lighted include the Town Hall, market, and two churches. In contrast to the plan at Taunton, all wires are conveyed underground in 3in. iron pipes, and some unsightliness is thereby avoided, though at an increase in the original cost. The underground service appears to be carried on with perfect efficiency, and certainly with none of the drawbacks experienced at Leamington, and there often attributed to the difficulty of underground insulation. The arc lamps are still run from the Brush dynamos, but the incandescent lamps are fed from the dynamos on the alternating current system, with transformers, for which it is claimed that unvarying steadiness and perfect control are thereby secured. The current is governed by an automatic regulator, delicate and beautiful in its operation, and a peculiarity of the Lowrie-Hall system. The quality of the light produced, so far as the incandescent lamp is concerned, can be spoken of with unqualified praise. The arc lights, though more powerful than those at Taunton, do not at present compare favourably with them, the carbons being apparently of lower quality, and the lanterns comparatively ill-cared for. This is avowedly due to the low cost at which they are supplied. The present charge is £20 per lamp per annum, but the Corporation are about to increase the payment to £30 per lamp in return for an increase of power and efficiency which there will be no difficulty in ensuring with the improved appliances of the Lighting Company. The cost of lighting the area over which the lamps extend is necessarily larger than formerly by gas, but the amount of light given is about twenty times that of the former illuminant. The light is supplied to the private consumers by meter, at the rate of 1s. per standard, and each light being equal to 16 c-p. The present manager of the Eastbourne works is Mr. H. J. Harris, by whom the visitors from Cheltenham were received with the greatest courtesy. Before returning to Cheltenham, one portion of the deputation took the opportunity of visiting Hastings to see the electric light in operation there, and had reason to be pleased with the inspection, while a second party accepted an invitation to inspect the extensive works of the Brush Company at Lambeth."

UNIPOLAR INDUCTION.—I.

BY G. W. DE TUNZELMANN, B.SC.

If a magnetic pole in the neighbourhood of a conductor is made to vary in intensity, or if its position relative to the conductor is changed, then it is well known that an E.M.F. is produced in the conductor. Electric currents arising in this way are said to be due to magneto-electric induction; but, as was first observed by Faraday, electric currents may be produced in a conductor by means of a magnetic pole without either variation in its strength or in its position relative to the

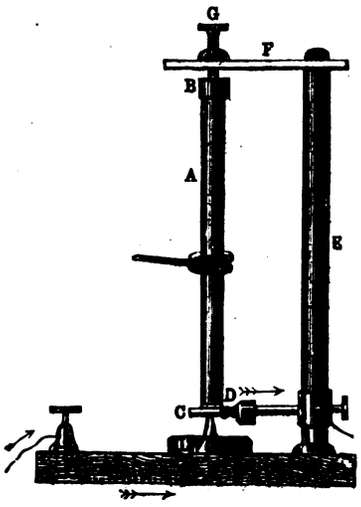

FIG. 1.

conductor. The name of unipolar induction is generally used to denote the production of electric currents under these circumstances. The term is a misleading one; but it has unfortunately come into general use.

In his second series of "Experimental Researches in Electricity," No. 217, Faraday points out that several of his experiments on terrestrial magneto-electric induction show that it is

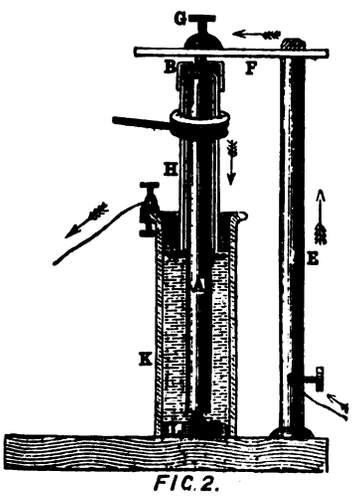

FIG. 2.

A, magnet; B, cap containing mercury; C, copper disc; D, tinfoil pad for rubbing contact; E, metallic pillar; F, horizontal metallic arm; G, metal pivot in electrical contact with F; L, metal pivot; H, copper cylinder separated from magnet by intervening paper; K, metallic vessel containing mercury.

not necessary for the production of a current that the moving conductor should, in cutting the lines of force of the terrestrial magnetic field, pass into positions of greater or less magnetic force; for example, the currents produced in a copper plate or sphere rotating in the earth's magnetic field, or in a wire moving across the earth's lines of force ("Experimental Researches," Ser. II., Nos. 149, 161, 171), were all produced in a practically uniform field.

These considerations led Faraday to attempt to obtain similar phenomena by means of an ordinary magnet, and the details of his experiments, made in 1832, are described in his second series of "Experimental Researches," Nos. 218 to 230: his later researches in the same subject, in 1851, are given in the twenty-eighth series, Nos. 3,084 to 3,122. The discovery of what is now known as Unipolar Induction was due, then, to Faraday, and though he did not give any special name to the group of phenomena, his researches form the basis of all subsequent work. We shall therefore begin by following pretty closely his series of experiments, though using somewhat more convenient arrangements.

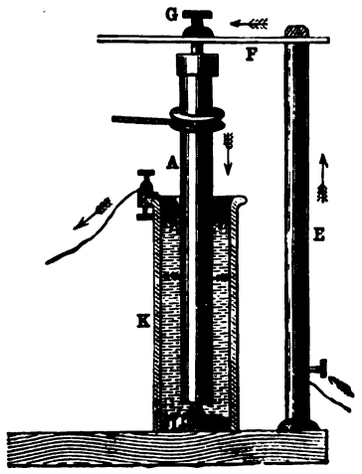

FIG. 3.

A, magnet; B, cap containing mercury; C, copper disc; D, tinfoil pad for rubbing contact; E, metallic pillar; F, horizontal metallic arm; G, metal pivot in electrical contact with F; L, metal pivot; H, copper cylinder separated from magnet by intervening paper; K, metallic vessel containing mercury.

A copper disc is cemented to the end of a cylindrical bar magnet, being insulated from it by an intervening sheet of paper. The magnet is then inserted tightly into a grooved wooden pulley, and its free end is provided with an open cylindrical cap to hold mercury for the purpose of making better contact.

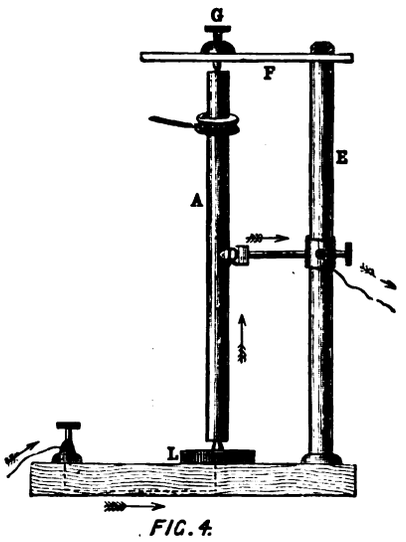

FIG. 4.

A, magnet; B, cap containing mercury; C, copper disc; D, tinfoil pad for rubbing contact; E, metallic pillar; F, horizontal metallic arm; G, metal pivot in electrical contact with F; L, metal pivot; H, copper cylinder separated from magnet by intervening paper; K, metallic vessel containing mercury.

Small holes are then made in the centres of the free end and of the copper disc, and the magnet is then pivoted, as shown in Fig. 1, to allow of its being set in rotation. A collector, consisting of a pad of tin foil, is made to press against the periphery of the disc, and wires are led from the rubber and from the lower pivot to a galvanometer. When the magnet is made to rotate a continuous current is produced through the galvanometer, which increases in strength with the speed of

Digitized by Google

rotation, and changes its direction when the direction of rotation is reversed. The current is also reversed when the polarity of the end in contact with the disc is reversed.

These phenomena are exactly similar to those which would be observed if the magnet were fixed and the disc alone were made to rotate, and show that, as in this case, a radial E.M.F. is produced in the disc. If the disc is fixed and the magnet made to rotate no current is observed.

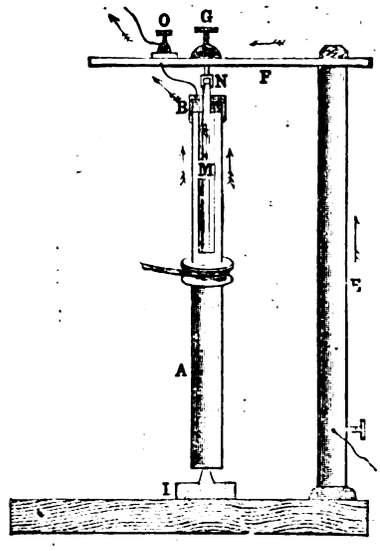

FIG. 5.

An arrangement giving somewhat stronger currents, owing to there being better contact, is shown in Fig. 2. The lower pivot is here surrounded by a hollow cylinder, open at both ends, which fits tightly over the cylindrical base of the pivot, and the upper half of the magnet is enclosed in a copper

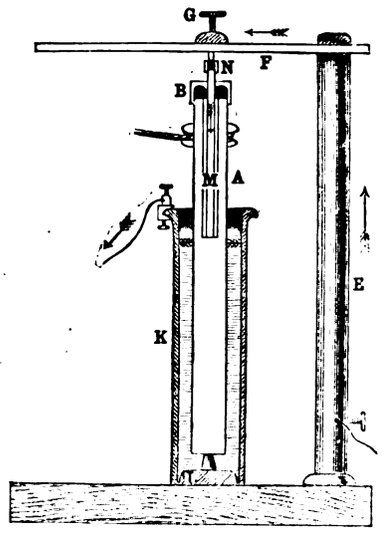

FIG. 6.

cylinder closed at one end, and insulated from it by means of paper. The closed end of the cylinder is provided with an open cap containing mercury.

These experiments naturally suggest that the same phenomena would be observed with the magnet alone without the intervention of either cylinder or disc, and this is found to be the case. Fig. 3 shows the arrangement adopted. In the two latter forms of the experiments it is found that with a given speed of rotation the current is strongest when the surface of the mercury is at the centre of the length of the magnet, and falls almost to zero when the mercury only just covers the end of the magnet, or when the magnet is almost completely immersed.

Exactly similar phenomena may be observed without the use of mercury with the arrangement shown in Fig. 4, where a rubbing contact is used, as in the first experiments.

Here again we find, as we should expect from the preceding experiment, that the strongest currents are obtained when the rubber is in contact with the central portion of the magnet.

In order to show that the E.M.F. is entirely radial and not such as to produce a current down the axis of the magnet and up the external portions, or *vice versâ*, Faraday devised a most ingenious arrangement, shown in Fig. 5.

The central portion of one end of the magnet is bored out, the hollow extending nearly to its centre. A copper rod is then inserted into the hole thus formed and allowed to project beyond the magnet, from which it is insulated by a layer of paper. The free end of this rod and the hollow end of the magnet are both provided with caps to hold mercury. The magnet may conveniently be mounted as shown in Fig. 5. The axial contact is made by means of the upper pivot, and the other one by means of the bent wire shown in the figure, dipping

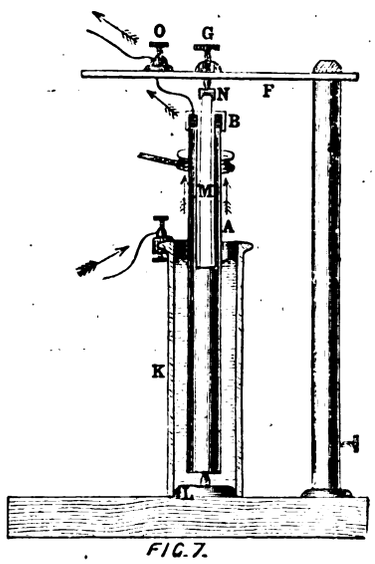

FIG. 7.

A, magnet; B, cap containing mercury; C, copper disc; D, tinfoil pad for rubbing contact; E, metallic pillar; F, horizontal metallic arm; G, metal pivot in electrical contact with F; L, metal pivot; H, copper cylinder separated from magnet by intervening paper; K, metallic vessel containing mercury; M, copper rod; N, cap containing mercury; O, binding screw insulated from the arm F

into the mercury contained in the cap attached to the magnet. This wire and the binding screw to which it is attached must, of course, be insulated from the portion of the metallic framework which supports it. When the magnet is rotated the current must pass down the copper rod and up the outer portions of the magnet, as indicated by the arrows.

The bent wire is now removed, and the lower half of the magnet is immersed in mercury, as shown in Fig. 6. If the magnet is now rotated in the same direction as before, a current is produced which is also in the same direction, but stronger, though the upper half of the magnet is entirely out of the circuit.

The bent wire is now replaced in its former position, but the other contact is made by means of mercury surrounding the lower half of the magnet, as shown in Fig. 7, so that the copper rod is now entirely out of the circuit. The current is still found to be in the same direction, and as strong as in the last experiment. We see, therefore, that the E.M.F. is entirely in a direction perpendicular to the axis of the magnet.

In the experiments hitherto described a cylindrical magnet has one end of its axis and the equatorial portion of its curved surface respectively in contact with the ends of a

Digitized by Google

fixed metallic circuit. Fig. 8 shows a form of apparatus in which the magnet may be made to revolve, while the metallic circuit remains fixed as before, or the circuit may be made to revolve while the magnet remains fixed, or the magnet and circuit may be fixed relatively to each other, and be made to revolve together.

A copper disc, g, is rigidly attached to a metallic axis mounted in such a way as to allow of its being made to rotate. Two equal magnets, N S, are fixed with similar poles in the same direction, parallel to this axis, equidistant from it, and on the same diameter. The axis of rotation may therefore be considered as the axis of the compound magnet so formed.

The axis passes through a collar, h, of hard wood covered with brass, and also carries a pulley rigidly fixed to the collar. The collar can be rigidly attached to the axis by means of the screw f, which does not place the collar and the axis in metallic connection. Rubbing contact can be made at l, m, n, and h, by tinfoil pads carried on brass strips, and a similar pad can be attached to the collar by the screw e, and make rubbing contact at g, as shown in the figure. We will, in the first place, remove the strip $e\,g$, screw up the collar to the axis and the pulley, and set the apparatus in rotation. If the terminals of a galvanometer are now attached either to b and c or to b and a, a current will be observed, increasing in strength with the speed of rotation, and its direction will be reversed if the direction of rotation is reversed, or if this remains the same and the two magnets are reversed. If the galvanometer terminals are attached to a and c no current will be observed. Now remove the rubbers m and n, unscrew the collar from the axis and screw on the brass strip $e\,g$, connect a and d with the terminals of a galvanometer, and fix the axis to the bearings (by means of a screw not seen in the figure) so that it cannot revolve with the collar. If the collar is now made to revolve a current will be produced the same in direction and strength as if the axis carrying the magnets had been made to revolve with the same speed in the opposite direction. If we now loosen the screw which fixes the axis, and screw the collar to the axis, so that the strip $e\,g$ and the magnets rotate together without any change in their relative positions, we shall not be able to obtain any current on connecting the galvanometer terminals with a and d as before.

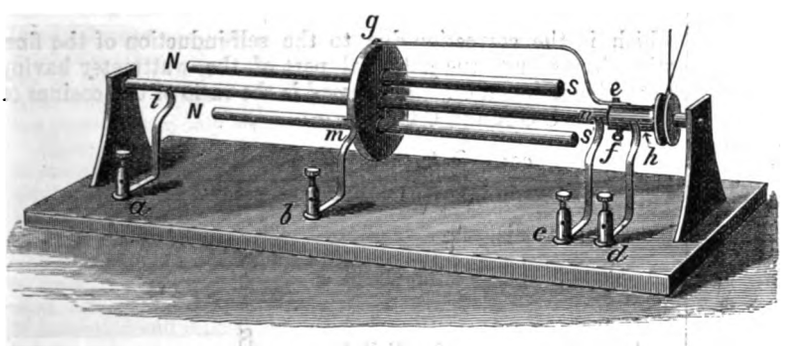

FIG. 8.

The results of these last three experiments confirm the conclusion previously arrived at, that the E.M.F. is entirely at right angles to the axis of the magnet, and in addition they appear to prove decisively that the current is due entirely to the motion of the magnet relatively to the rest of the conducting circuit, so that the lines of force due to the magnet must be considered to be rotating with it.

(To be continued.)

Bank of England.—Owing to the successful working of the 500-light extension at the Bank of England, the directors have decided to adopt the electric light for the new branch bank which is being built at the Law Courts. Messrs. Drake and Gorham are fixing a nine horse-power gas engine, and a twelve-unit Elwell-Parker dynamo of the latest type for this work.

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(Continued from page 75.)

The action of these two causes of error may be illustrated and explained best by the geometric method.

Describe a circle with centre O (Fig. 39), and take any line O A to represent the maximum value of the potential difference between the two points M M′ of the divided circuit, of which R is the resistance of the inductive circuit consisting

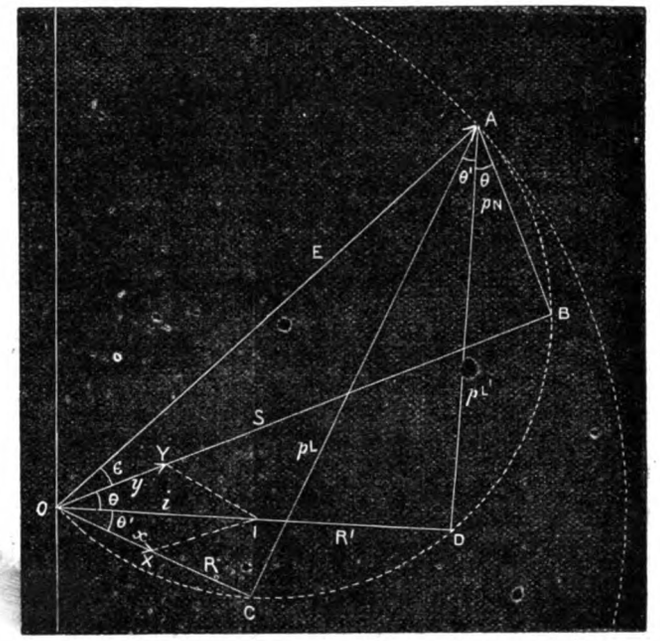

FIG. 39.

of the thick wire of the watmetter in series with the circuit in which the *power* is being measured, and S that of the fine wire of the wattmeter. Then, as before, the vertical projections of O A as it revolves represent the periodic variation of this potential difference. On O A describe a semi-circle, and set off on O A as a base two right angle triangles O C A, O B A, of which the sides O B, B A, and O C, C A are in the ratio respectively of the ohmic to the inductive resistances of these circuits. Otherwise the angle A O B is one whose tangent is p times the time-constant of the S circuit, and A O C is one whose tangent is p times the time constant of the R circuit. Take one Sth portion of O B, and set off O Y equal to it, then, as on p. 504, Vol. XX., O Y represents the maximum value of the current in the S circuit.

Similarly, set off O X equal to one Rth part of O C, and O X represents the maximum current in R. On O X, O Y, describe a parallelogram O Y I, and draw the diagonal O I, and produce it to O D. Then O I represents the maximum current just before division on the main currents. Join A D, A D and O D will represent the compound or equivalent inductive and ohmic resistance of the two circuits R and S in parallel.

To prove this last proposition, we must refer again to the paper by Lord Rayleigh on "Forced Harmonic Oscillation of Various Periods" (*Phil. Mag.*, 1886).

If R′ represents the equivalent resistance of a number of resistances joined in parallel between two points, and L′ represent the equivalent inductance of the system, then it is shown in this paper that

$$R' = \frac{A}{A^2 + p^2 B^2} \text{ and } L' = \frac{B}{A^2 + p^2 B^2},$$

where

$$A = \Sigma \frac{R}{R^2 + p^2 L^2},$$

and

$$B = \Sigma \frac{L}{R^2 + p^2 L^2}$$

Digitized by Google

R and L being the resistance and inductance of any branch, and mutual inductance being zero.

Apply this theorem to the case under consideration of the two inductive resistances (R, L) (S, N) in parallel, we have

$$A = \frac{R}{R^2 + p^2 L^2} + \frac{S}{S^2 + p^2 N^2}$$

$$B = \frac{L}{R^2 + p^2 L^2} + \frac{N}{S^2 + p^2 N^2}.$$

Effecting the multiplication we have

$$A = \frac{R(S^2 + p^2 N^2) + S(R^2 + p^2 N^2)}{(S^2 + p^2 N^2)(R^2 + p^2 L^2)}$$

$$B = \frac{L(S^2 + p^2 N^2) + N(R^2 + p^2 L^2)}{(S^2 + p^2 N^2)(R^2 + p^2 L^2}$$

and $$R' = \frac{A}{A^2 + p^2 B^2} = \frac{R(S^2 + p^2 N^2) + S(R^2 + p^2 L^2)}{(R+S)^2 + p^2 (L+N)^2}$$

$$L' = \frac{B}{A^2 + p^2 B^2} = \frac{L(S^2 + p^2 N^2) + N(R^2 + p^2 L^2)}{(R+S)^2 + p^2 (L+N)^2}.$$

Turning back to Fig. 39 we see from the geometry of it that if the angle B O D is as before called θ that B O D = D A B.

Hence $$\frac{OD}{\cos\theta} = S - p N \tan\theta,$$

since A B = p N and O B = S by construction,

therefore $$OD = S\cos\theta - p N \sin\theta,$$

On page 736, Vol. XX., we have found the value of tan θ to be

$$\tan\theta = \frac{(SL - RN)p}{R(R+S) + L(L+N)p^2};$$

hence substituting we have

$$OD = \frac{S\{R(R+S) + L(L+N)p^2\} - p^2 N(SL - RN)}{(R+S)^2 + (L+N)^2 p^2};$$

or $$OD = \frac{RS(R+S) + p^2(SL^2 + RN^2)}{(R+S)^2 + (L+N)^2 p^2}.$$

On comparing this value for O D with the value above calculated for R′ we see they are equal, and hence O D = R′.

So that on the same scale on which O B and O C represent S and R the individual resistances O D represent the equivalent resistance for the periodicity employed. Similarly, it may be shown that A D = p L′ for the angle C O D = θ' = angle C A D, and

$$\frac{AD}{\cos\theta'} = pL - R\tan\theta',$$

or $$AD = pL\cos\theta' - R\sin\theta';$$

and since $$\tan\theta' = \frac{(RN - SL)p}{S(R+S) + N(L+N)p^2},$$

a similar substitution enables us to see that

$$AD = \frac{pL(S^2 + p^2 N^2) + pN(R^2 + p^2 L^2)}{(R+S)^2 + (L+N)^2 p^2},$$

and this is equal to the value found by analysis for p L′.

The diagram also shows us many other things besides this construction for the equivalent resistance and inductance.

It shows us for instance precisely what is the effect of the inductance of the wattmeter fine-wire circuit, and what must be the correction applied to the readings to get the real power expended in the induction circuit.

The actual reading of the wattmeter is proportional to the true mean value of the product of x or the current in the inductive circuit R, and y or the current in the fine-wire circuit S; and this as previously shown is equal to half the product of their maximum values, and the cosine of the difference of phase.

From Fig. 39 this mean value is therefore

$$\frac{OX \cdot OY}{2}\text{cosine BOC}.$$

This, however, is *not* the measure of the power expended in the R circuit. The true watts are proportional to the mean product of x and a current equal to one Sth part of e having a phase difference equal to the angle C O A, viz, that of the angle of lag of the current in R and the potential difference O A of its ends; hence the real power or watts are proportional to

$$\tfrac{1}{2}\frac{E}{S} \cdot OX \cdot \text{cosine COA},$$

since E is the maximum of e, viz., the instantaneous potential difference between the extremities of the branch circuits.

Now O Y is taken as one Sth part of the effective electromotive force in the S circuit; and on the same scale, on which O A represents the impressed E.M.F., O B represents the effective E.M.F. in that circuit. Hence, in taking the reading of the wattmeter, which is proportional to

the quantity $$\frac{OX \cdot OY}{2}\text{ cosine BOC}$$

as the watts, we are making an error, for the quantity really required is the value of

$$\frac{1}{2}\frac{E}{S}OX\text{ cosine AOC},$$

which is numerically equal to the real power. Hence two errors come in—one due to the maximum current in the fine-wire circuit being O Y or $\frac{OB}{S}$ instead of $\frac{E}{S}$ or $\frac{OA}{S}$, and the other due to the phase difference being taken as the angle C O B instead of C A O.

To correct the instrumental reading or observed watts to true value or real watts, we have to multiply the observed readings by two factors,

first, the ratio of $$\frac{OA}{OB}\text{ or }\frac{\sqrt{S^2 + p^2 N^2}}{S},$$

which is the correction due to the self-induction of the fine-wire circuit or to the potential part of the wattmeter having a sensible inductance. The *second* is the ratio of the cosines of the angles C O A and C O B or

$$\frac{\cos COA}{\cos COB} = \frac{\cos COA}{\cos(COA - BOA)} = k,$$

but from the diagram

$$\text{cosine COA} = \frac{R}{\sqrt{R^2 + p^2 L^2}},$$

and $$\text{cosine BOA} = \frac{S}{\sqrt{S^2 + p^2 N^2}}$$

$$\therefore k = \frac{\dfrac{R}{\sqrt{R^2 + p^2 L^2}}}{\dfrac{R}{\sqrt{R^2 + p^2 L^2}} \cdot \dfrac{S}{\sqrt{R^2 + p^2 L^2}} + \dfrac{pL}{\sqrt{R^2 + p^2 + L^2}} \cdot \dfrac{pN}{\sqrt{S^2 + p^2 N^2}}}$$

Combining these two corrections into a single product, we get as the full correcting factor:—

$$\frac{\sqrt{S^2 + p^2 N^2}}{S} \cdot \frac{R\sqrt{S^2 + p^2 N^2}}{RS + p^2 LN}$$

or $$\frac{RS^2 + p^2 N^2 R}{RS^2 + p^2 LNS} = F.$$

If we put $T_s = \frac{N}{S}$ where T_s is the time-constant of the S circuit, or the fine wire circuit, and $T_R = \frac{L}{R}$ where T_R is the time-constant of the R circuit, we have

Digitized by Google

$$F = \frac{1 + p^2 T_S^2}{1 + p^2 T_R T_S},$$ *

and the real watts or power taken up in the circuit R is real watts = observed watts × F. F becomes unity for two cases when L and N are both zero, and also when $T_S = T_R$.

Hence, the ordinary wattmeter, applied as usual to measure the *electrical power* in a circuit traversed by a simple periodic current, gives absolutely correct readings only in two cases. First, when the fine-wire circuit and the circuit being measured have no inductance; second, when the fine-wire circuit and the circuit being measured have equal time-constants.

But if T_R is greater than T_S, then F is a proper fraction. The wattmeter reads too high, and the real watts are less than the observed. If T_R is less than T_S, then the observed readings are too low. If $T_R = T_S$, then the observed readings are correct. Hence the wattmeter may read too high, too low, or correct. Generally speaking, it reads too high, since the time-constant of the measured circuit will be in excess of that of the fine wire circuit.

(To be continued.)

UNDERGROUND ELECTRICAL CONDUCTORS IN EUROPE AND AMERICA.†

BY PROF. G. W. PLYMPTON.

The problems of construction of underground systems of electrical conduction will have been solved when the telephone and the arc light systems are both buried under our streets without impairing the efficiency or durability of either.

By this I mean that all the difficulties encountered in burying conductors are involved in converting telephone and arc light from *aerial* to *underground* systems. Telegraph lines and systems of incandescent lighting present fewer difficulties in the process of burying, and none of a kind not met with in dealing with the systems first mentioned.

The telephone problem is substantially solved. Some details only remain to be settled, among which may be mentioned the best size of conductor, the most serviceable insulation, and the maximum distance of effective service for either grounded or metallic circuits.

In Brooklyn, the general plan adopted is that of a conduit divided into ducts through which cables containing from sixty to one hundred wires are drawn. The material of the conduit is for the most part creosoted wood. About ten miles of this is already in use in our city, and about four and a-half miles of the Dorsett concrete conduit. For the extensions of the underground systems for the present year only creosoted timber is to be used.

Among the lessons learned from our experience are:—1st. That in creosoted conduits the use of cables covered with kerite, or any similar rubber or gutta percha compound, must be avoided. 2nd. That in the so-called lead-covered cables, the use of pure lead is also to be avoided, as it is slowly converted into a porous and friable lead carbonate. An alloy of lead with five or six per cent. of tin seems to resist the destructive action. 3rd. That the conducting wire first used is too small for satisfactory telephone service. The difficulties of induction and retardation led to complaints as soon as 4,000 or 5,000ft. of underground wire was put in service. The cables that are now being put in are made up of wires whose cross-section is greater by one-third than that of the first wire, and they are protected by twice the thickness of insulation.

I mention the above conclusions as having been drawn from our own experience in Brooklyn.

In commencing our work we gathered such information as could be gleaned from localities where solutions of the problem had already been attempted. The impression so largely prevailed that in Europe all telephone and telegraph conductors were underground that our Board decided that a personal inspection of European systems should be made by one of our number. The duty devolved upon me. The result of my inquiry has been published in the scientific papers.

I will briefly refer to a few of the incidents. [Prof. Plympton here gave an epitome of the third annual report of Brooklyn Subway Commission, which embodied his observations.]

In regard to the burial of the arc light wires I can only say that no method yet tried seems certain of success. Most of them certainly ensure the destruction of the underground conductors in from one to three years. But I have no doubt that a solution of the problem will soon be reached, although the system will be kept apart from the telephone and telegraph subway.

It does not seem likely that arc light conductors will be allowed in the same conduit with telephone wires, nor will they be distributed from the same manholes.

In saying that, I believe that a solution of the problem will soon be found. I do not mean to assert that casualties like that recently recorded of a man in the Bowery, who lost his life by grasping the naked wire close to an arc lamp, can be prevented by any system of burying wires. To prevent such *accidents* (if that is the term to be used) the arc lights must be buried with the wires.

All past experience teaches us to proceed cautiously. Nothing can now permanently check the growth of the telephone, the telegraph, or the electric light. They have become necessities of our civilisation, and any hasty or ill-advised enforcement of the law to convert all aerial to underground systems which should result in serious injury to them, would prove the surest way to perpetuate the nuisances of overhead wires and poles in the streets.

* This expression for the ratio of the real watts to the observed watts was given by Prof. Ayrton in the discussion of Mr. Kapp's Paper on "Transformers," read at the Society of Telegraph-Engineers, Feb. 16th, 1888. (See *Journal* of the Society of Telegraph-Engineers, Vol. XVII., p. 173.) Prof. Ayrton did not, however, at that time give the reasoning by which he established it, and the above geometrical method occurred to the writer in subsequently considering it.

† Read before the American Institute of Electrical Engineers, May 16th, 1888.

BOOKS, &c., RECEIVED.

"Séances de la Société Française de Physique." July to December, 1887. (Paris: Imprimerie de Gauthier Villas.)

"Anuario del Observatorio Astronómica Nacional de Tacubaya," for the year 1888. (Mexico: Calle de San Andrés.)

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, June 8th.

ROYAL INSTITUTION.

9 p.m. Lecture on "Phosphorescence and Ozone." By Prof. DEWAR, M.A., F.R.S, M.R.I.

SATURDAY, June 9th.

ROYAL INSTITUTION.

3 p.m. Lecture, "Count Tolstoi as Novelist and Thinker" (2). By Prof. C. E. TURNER, of the University of St. Petersburg.

PHYSICAL SOCIETY (Normal School of Science, Exhibition-road, South Kensington).

3 p.m. "On the Analogy betweeen Gases and Substances in Dilute Solutions." By Prof. J. H. VAN 'T. HOFF. Communicated by Prof. W. RAMSAY. Exhibition of a Lantern by Mr. W. LANT CARPENTER.

TUESDAY, June 12th.

ENGINEERING SOCIETY (King's College, London, W.C.).

4 p.m. Business Meeting.

THURSDAY, June 14th.

ROYAL SOCIETY.

4:30 p.m. Ordinary Meeting.

SATURDAY, June 16th.

ROYAL INSTITUTION.

3 p.m. Lecture, "Count Tolstoi as Novelist and Thinker" (3). By Prof. C. E. TURNER, of the University of St. Petersburg.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* THE PROPRIETORS.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
,, Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY

VOLUME XX. OF "THE ELECTRICIAN"

NOW READY. Bound in cloth, price Ten Shillings and Sixpence.
Also Cases for Binding, price Two Shillings.

Applications should be made to "The Publisher."

ELECTRICAL INTERESTS IN AMERICA.

While the relations between Electrical Engineers on the one hand, and Fire Insurance Offices and their clients on the other, have been undergoing prolonged discussion in this country, a satisfactory adjustment of their differences remaining as far off as ever, the States of New England appear to have settled these matters for themselves in a way which is at once surprising and instructive. In another portion of our present issue will be found the leading features of an association which bids fair to become a model for similar organisations throughout the United States, and which at the present juncture deserves the careful attention of electrical engineers in this country. The scheme of the "New England Electric Exchange" originated in much the same condition of affairs as that which has so long occupied the attention of the Society of Telegraph-Engineers and Electricians. In America the operations of electrical business have, of course, been more extensive, and possibly the work has not been so well done as, on the whole, it has been with us. But the difference is only in degree, the same defects being conspicuous in both countries, and leading to the same evil consequences. Installations of electric lighting and electrical power supply have fallen not infrequently into incompetent hands; customers have been disappointed with the results; insurance offices have declined to accept responsibility, and generally a feeling of insecurity has arisen, which, if allowed to go on uncorrected, may permanently prejudice the electrical industries. Such, at all events, is admitted to be the case in America; and in order to re establish public confidence by more stringent control over their profession, this association of electrical engineers has been instituted in New England.

Its leading objects, as set forth in Article II. of the proposed "Electric Exchange," are the promotion of electrical business, and "especially in the direction of securing perfection in electric light and electric power installations, and in har-

Digitized by Google

monising and adjusting as far as possible all differences which may arise between various electrical interests." With regard to the latter part of the clause, the necessity for it is more pressing in the States than it is here, where the Government owns the greater part of the telegraph wires, and is amply protected against any injurious conflict of interests. But in the main, it will be seen, the New England scheme resembles very closely and will occupy a similar position to that which the "Association of Electrical Engineers" would have now occupied in this country had its conception been realised last year. As regards that abortive project we need only remark that the Society which was foremost in opposing it has since had an experience which ought to satisfy it that the functions of a trade society cannot be performed with efficiency or dignity by a scientific body whatever may be its title. Among the American electrical engineers there are no delusions of this kind. They mean business, and set about it with more directness and boldness than has ever been openly advocated even in these pages.

From a circular which accompanies the Articles of Association, and for the advanced proofs of which we are indebted to our Boston contemporary, *Modern Light and Heat*, we learn that the formation of the New England Electric Exchange has been the result of various conferences held between gentlemen interested in insurance matters and others engaged in electrical business. At these conferences the subject of "diminishing risks to property and life by a more thorough installation of electric light and power plants, and the employment of the most competent men, were discussed." One result of these discussions was the adoption of a "plan of licensing" competent men for the work they propose to undertake. We are not informed as to the details of the discussion; but we can easily imagine the course it would take. First of all there must be established an authoritative and trustworthy body of men associated and empowered to issue these licenses. Apparently no difficulties were experienced in that direction; and having settled this point, the next thing to be considered was to enforce the "plan of licensing" as an imperative condition of employment. The license would always be of some value; but unless the man who held no license could be prevented working, the credit of the profession would still be at his mercy. Happily the good relations which subsist between the insurance offices and the leading electrical engineers have enabled them to overcome this difficulty in a manner which to us seems almost sublime. The circular from which we have already quoted proceeds to announce that "After October 1st, 1888, the fire underwriters will not insure any property where electric light or electric power is used, nor pass any new installations, unless the party operating the plant or making the installation has obtained from this exchange a certificate of license."

If both sides to this bargain hold to the terms of it—or, more exactly, if the insurance offices, as well as their agents, are satisfied with the character of the licenses issued by the Electric Exchange, the effect must certainly be precisely what the latter desire, namely, the exclusion of incompetent workmen. The attainment of that object whenever hinted at in this country has been contemptuously rejected as in the nature of boycotting. In reality it no more deserves that reproachful designation than does the diploma of a medical man, or the barrier which hedges the profession of the law. The one and only thing needful in all such cases is that the examination shall answer its purpose—the purpose, namely, of excluding unauthorised and incompetent pretenders. Whether the examination proposed by the New England Electric Exchange will answer this description is a matter we need not stay to discuss. According to our ideas the mode of procedure is, perhaps, a little uncertain and liable to error. But experience will correct shortcomings of that description; and in the meanwhile an ingenious plan has been hit upon for lessening the burden of the examination, and rendering it available for all grades of knowledge and skill. Not every electrical workman or engineer is expected to be able to perform every kind of electrical work; but every holder of the Association's license is certified, after examination, as being able to do the class of work which he professes to do, and will be entitled to do no other. There are, in fact, five different classes of licenses, ranging from the first, which certifies the person "fully competent to install any electric light or power plant," to the fourth and fifth, which are issued respectively to persons competent to "operate electrical machinery," and "to do electric wiring." The examinations, therefore, are to cover not only the high-class electrician and electrical engineer, but the workpeople whom they employ; and it is obvious, if the tests are conducted with rigour and prudence, a general improvement in electrical workmanship all round may be anticipated. It would be idle to recommend this scheme for adoption here, where public feeling is against it, and where the conditions are not wholly identical. But we may watch the progress of it in the New England States with much interest, and probably with some profit.

REVIEWS.

Researches on Diamagnetism and Magne-Crystalline Action, including the Question of Diamagnetic Polarity. By JOHN TYNDALL, D.C.L., LL.D., F.R.S. New Edition. (London: Longmans, Green and Co. 1888.)

The phenomenon of diamagnetism was chosen by Tyndall as the subject of the first lecture delivered by him before the Royal Institution. This was in February, 1853, and a few months later (at the instance of Faraday) he was elected by the Institution to the Chair of Natural Philosophy. Tyndall continued for some years to devote himself to the study of diamagnetism, and contributed numerous Papers on the subject both to the Royal Society and to the *Philosophical Magazine*. In their collected form, these Papers were the first work of Tyndall's to issue from the press, and as a record of patient and laborious endeavour directed to the disentanglement of singularly complex and exceedingly delicate phenomena they will always occupy an important place in the history of experimental science. The electrician who values his acquaintance with the science solely for utilitarian ends may safely be recommended to neglect "the question of diamagnetic polarity"; but for those who cultivate the love of science for its own sake this will always be a delightful book.

It is, nevertheless, necessary to warn the student who reads the book for the first time in the new edition that he should be careful to discriminate between the *theory* and the *facts* therein set forth. The validity of the latter has been impeached by no experiment of subsequent date; but, on the other hand, it is necessary to say that the views of diamagnetic polarity adopted by Tyndall are by no means unreservedly accepted by later writers. The theory in question (which was also warmly advocated by Weber) supposes that the polarity acquired by a diamagnetic body in a given field of force is the reverse of that which would be acquired by a paramagnetic body under the same conditions. Faraday, on the other hand, denied that diamagnetism was a polar force at all; holding that the observed phenomena were simply due to a tendency in diamagnetic bodies to move from stronger to weaker parts of the magnetic-field. Faraday arrived at this view from a study of the behaviour of crystals in the magnetic field, which behaviour Plücker endeavoured to connect with the position of the optic axis. Tyndall, however, proved conclusively that the action, whether para- or dia-magnetic, is directed along the line of maximum density of the substance,

Digitized by Google

and is only incidentally connected with the direction of the optic axis in crystals. The essentially polar character of diamagnetism must be held, even in opposition to Faraday, to have been conclusively proved by the famous *experimentum crucis* of Tyndall. In this experiment a bar of bismuth was placed within a solenoid traversed by a powerful current; it was then found to be attracted by one pole of a magnet and repelled by the other, which is usually accepted as the test of "polarity." But it is, perhaps, still a little doubtful whether the controversy between Tyndall and Faraday arose from anything more than differences of definition and phraseology. Writing to Matteucci in November, 1855, Faraday himself said, "I differ from Tyndall a good deal in phrases, but when I talk with him I do not find that we differ in facts. *The phrase polarity in its present undefined state is a great mystifier.*"

At the present time, however, while we accept our facts unreservedly both from Tyndall and from Faraday, there is a strong tendency to adopt an hypothesis which consorts with the theory (or at least the phraseology) neither of the one nor of the other, but is that originally due to the elder Becquerel. Accustomed as we are to treat all magnetic problems by the Faradaic method of lines of force, an electrician of to-day simply stands aghast at such a diagram as that of Fig. 1,

Fig. 1.

taken from page 248 of the present edition of Tyndall's book. In fact, this mode of regarding diamagnetic phenomena is entirely inconsistent with the fundamental properties of lines of force. Faraday, on the other hand ("Experimental Researches," § 2,821), exhibits the different action of a paramagnetic and a diamagnetic body in a field of force by the following diagram (Fig. 2), in which the left-hand body is

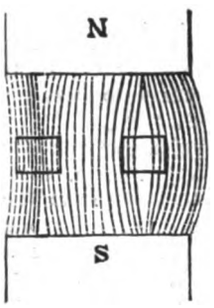

Fig. 2.

supposed to be paramagnetic and that on the right to be diamagnetic. This diagram is, so far as it goes, in accord with the hypothesis of Becquerel, which is simply that the magnetic permeability of paramagnetic bodies is greater than that of space (or of the ether), while for diamagnetic bodies the permeability is less than that of space; that diamagnetism is, therefore, a purely relative phenomenon, a substance appearing to be either paramagnetic or diamagnetic according as its permeability is greater or less than that of the medium in which it is placed. This explanation renders a satisfactory account, on the one hand, of Faraday's characteristic, namely, that diamagnetic bodies tend to move in the magnetic-fields from stronger to weaker places; and, on the other hand, it is quite in accord with the *experimentum crucis* of Tyndall. It will be found a most interesting exercise for the student to endeavour to apply this explanation to the experiments which Tyndall adduces in support of the theory of Weber, or in opposition to the views of Faraday. It is interesting also to note in passing how Tyndall, not having accustomed himself at that time to the delineation of magnetic fields, found it necessary to plot out some very simple cases by means of laborious experiment—cases in which the general character of the field would now be understood at a glance (*see* p. 103).

But, however much the simplicity and homogeneity of Becquerel's theory may tend to prejudice one in its favour, it cannot be said that the question has even yet been finally set at rest. Even if the whole of Tyndall's experiments are accounted for, there remains the fact that with diamagnetic substances the plane of polarisation is rotated in the opposite direction to that of paramagnetics. There is, however, no doubt that the more recondite problems of magnetism cannot be properly handled without a fuller recognition than is usually made of the distinction between the *inducing* and the *induced* fields. Becquerel's theory ought, probably, to be re-stated in a form in which it would be shown that the induced field of a paramagnetic body is stronger (or contains more lines per unit area) than the inducing field; while in diamagnetics the induced field is relatively weaker. On this assumption we believe that Prof. Ewing has been able to explain the difference in the direction of rotation of the planes of polarisation, without assuming an intrinsic difference in the sign of magnetisation. Meanwhile, we may at this point quote the following words of Tyndall, written in November, 1855, but which seem to us to convey a lesson which very many of us need to learn to-day:—"The cause of science is more truly served, even by the denial of what may be a truth, than by the indolent acceptance of it on insufficient grounds. Such denials drive us to deeper communion with Nature, and compel us through severe and laborious enquiry to strive after certainty, instead of resting satisfied, as we are prone to do, with mere probable conjecture."

In conclusion, one word may be said about that term which Faraday justly accused of being "a great mystifier." The Faradaic conception of the magnetic field has nowadays been so thoroughly absorbed and assimilated, and we have so many continuously recurring opportunities of verifying our deductions therefrom, that in spite, perhaps, of the warning just quoted, we are tempted to rest satisfied with any explanation or definition which can be harmonised with it. There is only one possible definition of polarity in terms of lines of force. Since lines of force are always closed curves every line which enters a body from without must also leave it again; the points of ingress and egress of the lines are points of opposite "polarity," and the essentially dual nature of the phenomenon is thus conformed to. In this sense Faraday was wrong in denying polarity to diamagnetics, but we think that Tyndall is wrong also if he still maintains that diamagnetic polarity is (in the same sense) opposite to that of paramagnetics.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

Chapter IX.—*Magnetic Fields (Continued).*

(Continued from page 48.)

110. *The Magnetic Meridian.*—At any given place on the earth's surface the magnetic meridian is the vertical plane (through that place) in which the total intensity of the earth's magnetic field is a maximum. Of the two component intensities, the horizontal and the vertical, into which, as before shown, the earth's field may be resolved, the former is necessarily a maximum in the same vertical plane as the total intensity, viz, in the magnetic meridian; hence the direction of this meridian may be seen by the direction in which a horizontally-pivoted magnetic needle sets itself, while the latter component, viz., the vertical, is the same in intensity in all vertical planes at one place. If, for example, we take a vertically-pivoted magnetic needle, whose horizontal axis of motion is through its centre of gravity, and move it round bodily, so that the vertical plane in which the needle moves is gradually altered until a vertical plane is found, in which the needle comes to rest in an absolutely vertical position, we know that the plane so found is at right angles to that of the magnetic meridian, because it is only in this plane that the horizontal intensity could be *nil*, and the vertical alone act.

Digitized by Google

Having found this plane in the foregoing manner, we know that the magnetic meridian is in a plane 90 degrees removed from it. This method of determining the plane of the magnetic meridian is employed at Kew Observatory, in order to place the "dipping needle" correctly in that plane before taking readings of the angle of "dip" or "inclination." Full descriptions of the instruments employed, and the methods of measuring the horizontal intensity, and the angles of inclination and declination, with the corrections to be taken into account, will be found in Gordon's "Physical Treatise on Electricity and Magnetism," Vol. I., and in Stewart and Gee's "Elementary Practical Physics," Vol. II. The plane of the magnetic meridian does not always coincide with that of the geographical meridian as determined astronomically. From data accumulated since 1576 it is found that in London the magnetic and geographical meridians coincide about every 320 years. Since their coincidence 231 years ago the magnetic meridian became more and more west of the true meridian, until, after a period of 160 years, a maximum was reached, and it then commenced to return. The angle between the two meridians is called the angle of *declination*, and is now in London 17° 40′ west. It will also be understood that the intensity of the horizontal magnetic field varies according to the latitude; for instance, on the magnetic equator, or line of no dip, the horizontal intensity is equal to the total intensity, and the further north or south we go the weaker does the horizontal intensity become, the difference in its value being noticeable even in Great Britain, where, for instance, its value in the town of Inverness is ·15 C.-G.-S. units, while in London it is ·18, the difference of latitude being about 6 degrees.

111. *Uniform Magnetic Field.*—A Magnetic Field is said to be "*uniform*" when the force exerted on a magnetic pole of given strength is the same at all points in that field. Throughout the space described by the movement of any given magnetic needle suspended or pivoted horizontally, as in galvanometers and indicators, we may regard the earth's horizontal field H as absolutely constant in value, in other words, such a needle is suspended in a "uniform" field, and the force exerted on its two poles would be the same for all positions it could possibly take up. The number of lines of force per square centimetre would also, by definition, be constant at all points in a uniform field, and therefore the lines of force would necessarily be parallel lines.

112. *Comparison of the Intensities of Magnetic Fields.*—The relative intensities of two or more magnetic fields, or the relative strengths of field at two or more different points in a magnetic field which is not uniform, may be determined by the method of vibrations. A small magnetic needle, horizontally suspended or pivoted, is placed successively at the points where the magnetic fields are to be compared, and after having been set oscillating the number of oscillations made in a given time are counted. The cause of the oscillations is evidently the magnetic force (equal to the product of the strength of one pole of the needle and the strength of the field) acting at both ends of the needle, and tending to bring it to rest in a line parallel to the lines of force of the field. If there were no force there would be no oscillation. We can observe this by annihilating the force acting on the needle.

FIG. 70.

An ordinary compass needle, if turned round out of the magnetic meridian and then allowed to swing, will continue to oscillate about the meridian till it finally comes to rest in it. The force causing these oscillations can be weakened or annihilated by destroying *either* of the two factors composing it. That is, we may do away with the force by destroying either the magnetic field or the strength of the needle poles. If the needle *n s* (Fig. 70) is lying in the magnetic meridian, the earth's field H (shown by the straight arrows) may be neutralised by approaching a magnet, N S, which sets up in the neighbourhood lines of force (shown by the curved arrows) opposite in direction to those of the earth. As the magnet is approached, if the needle is turned round its centre and then allowed to oscillate back, it will be found that the oscillations become more and more sluggish, and a point will at length be reached when the needle will not oscillate at all, but remain in any position it is turned to. This principle of weakening the earth's directive force on a needle by means of a magnet placed, as shown, in the neighbourhood is employed sometimes with galvanometers, where it is required to render the instrument more sensitive, and increase the amplitude of the deflections with weak currents.

Or, again, we may destroy the force by demagnetising the needle—that is, doing away with the other factor on which the force depends. If the needle is demagnetised completely, as may be done by placing it within a helix, or coil of insulated wire, through which an alternating current is passing, or what is the same thing if, instead of the magnetised needle, we substitute a piece of hard steel unmagnetised, we find that it will remain still in any position in which it may be placed; in other words, there is no force acting on it, and therefore the needle does not oscillate or take up a definite position. We have a mechanical example of this when a body is suspended vertically at the end of a length of fine thread. The top end of the thread being fastened to some fixed point, if the body is raised a little with the thread taut and then let go we have a pendulum action, and oscillations take place till the pendulum finally comes to rest in the vertical line of the earth's gravitation field of force.

In a similar manner to the magnetic needle above, we have here a force acting on the body, causing its oscillations, and composed of two factors, viz., the mass of the body and the acceleration of gravity. If we could destroy either factor, oscillation would cease, in consequence of the absence of any force. The mass of the body could only be dispensed with by removing the body altogether from the thread, which would then do away with the force and the resulting oscillations. We could not, however, neutralise the effect of the acceleration of gravity by a counter field of force in the same manner as a magnetic field.

Incidentally, here, attention may be drawn to the analogy between a mechanical and a magnetic field of force. Mass in the one is analogous to strength of pole in the other, and acceleration in the one (force divided by mass) is analogous to intensity of field in the other (force divided by pole strength). If there could be such a thing as a separate pole it would move along a line of force in a uniform magnetic field at a constantly increasing velocity or acceleration.

We now come to the well-established law of compound pendulums, viz., that the value of a force causing such oscillations (when these are of small angle) is proportional to the square of the number of complete oscillations in a given time, or inversely proportional to the square of the time during which a given number of complete oscillations are made. The time of a complete oscillation or "period" is taken from the instant the needle passes a given point to the instant it reaches the same point again, moving in the same direction.

Suppose the intensities at two points, A and B, in a magnetic field are to be compared. If at A a magnetic needle makes, say, 60 oscillations per minute, and at B the same needle makes 20 per minute, the fields at those points are respectively in the proportion of $60^2 : 20^2$—that is, as 9 to 1.

113. *Comparison of the Strengths of Poles of Magnets.*—By the same method we may compare the strength of pole of two or more magnets. Let a small horizontal compass needle be placed with its centre on a line drawn in the magnetic meridian. Turn it round its centre away from the meridian, and then let it swing. Count the number of oscillations, say 4 in 12 seconds—that is, 20 per minute in the earth's field alone. Now, suppose we have two long bar magnets, A and B, of equal length, whose pole strengths are to be compared. Place A on the line marked out, with its north pole pointing towards the south pole of the

Digitized by Google

needle; this increases the strength of field in the region of the needle, and it oscillates quicker, say 40 per minute. We have here two fields superposed in the region of the needle, each field being proportional to the square of the oscillations in a given time. The earth's field is then proportional to 20^2, and the two fields together proportional to 40^2; therefore the field produced by the pole of the bar magnet in the region of the needle is proportional to the difference of these squares $= 40^2 - 20^2$. Now remove A altogether, place B in exactly the same position, and count the oscillations, say 30 per minute. In a similar manner the field in the region of the needle due to the nearer pole of B is proportional to $30^2 - 20^2$. Now we have seen that the intensity of field at a point due to the pole of a magnet is equal to the strength of this pole divided by the square of the distance of the point from the pole. But the distance of the centre of the needle from the pole of each magnet in this case is the same, therefore the strengths of the respective poles are proportional to the respective intensities of field produced by each. We have therefore

$$\frac{\text{pole strength of A}}{\text{pole strength of B}} = \frac{40^2 - 20^2}{30^2 - 20^2} = \frac{1200}{500} = \frac{2\,4}{1};$$

or, making the calculation by the inverse ratio of the square of the time during which a given number of oscillations are made, we should have—

20 oscillations due to earth in 60 seconds
20 " " " A " 30 "
20 " " " B " 40 "

whence $$\frac{\text{field due to A and earth}}{\text{field due to earth}} = \frac{60^2}{30^2} = \frac{4}{1};$$

and therefore $$\frac{\text{field due to A}}{\text{field due to earth}} = 4 - 1 = 3.$$

Similarly $$\frac{\text{field due to B}}{\text{field due to earth}} = \frac{60^2}{40^2} - 1 = \frac{5}{4};$$

and, finally, the distance of the magnet poles of A and B from the needle being the same, the fields produced are proportional to their pole strengths. Hence—

$$\frac{\text{pole strength of A}}{\text{pole strength of B}} = \frac{3}{\frac{5}{4}} = \frac{2{\cdot}4}{1} \text{ as before.}$$

The kind of magnetic needle best suited for oscillation experiments is a short thick one—a piece of thick steel knitting needle not more than two centimetres long does very well—which can be magnetised in the ordinary way by stroking it over the pole of a permanent magnet, or by wrapping a layer of insulated wire round it and passing a current through the same, tapping the needle during the operation. If it is suspended, a convenient stirrup for it may be cut from a visiting card in the shape shown in Fig. 71, bending the ends over at

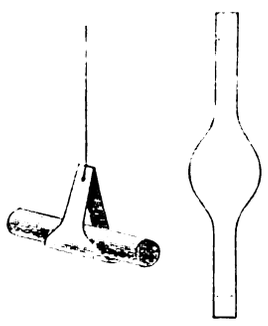

Fig. 71.

the dotted line, then piercing a hole through the four thicknesses of card and tying to it a fibre of unspun silk. Before the needle is put in the stirrup a somewhat heavier rod of non-magnetic metal, such as brass, should be hung and left for some time until all torsion is removed from the fibre. This will be the case when the weight comes to rest and remains so. The fibre should then be turned slightly till the length of the stirrup lies in the magnetic meridian and the magnetic needle inserted in it with its poles the right way. The needle is then lowered till it is just above a flat horizontal surface, such as a table or flat board, on which a card is placed with a black line drawn in the direction of the magnetic meridian. It is quite easy then to count oscillations every time the needle passes the black line going in a given direction. For greater delicacy a small circular mirror may be attached by beeswax to the fibre just above the stirrup, and a ray of light projected on to it from a lamp placed about two feet away, the lamp being surrounded by an opaque enclosure in which a narrow vertical slit is cut opposite the flame to emit the beam on to the mirror. The reflected ray thrown on to a white screen then shows the oscillations of the needle, and since these can be seen by this means when of very small angle, the arrangement is very sensitive, the meridian line for counting the oscillations being then marked vertically on the screen.

(To be continued.)

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

On Friday, in Mr. Justice Kay's court, the Attorney-General informed his Lordship that the final decision of the parties as to who should act as the umpires was not yet arrived at, but he handed in a list of suggested names for his Lordship to select from. His Lordship selected and ticked the names of the gentlemen who were to be asked to act in that capacity, but they were not made public at this stage of the proceedings; and as it was desired that experiments should still be made, which would occupy at least ten days, it was agreed that the case should stand adjourned until Monday, June 11th.

It was mentioned that the report would be drawn up by the gentleman hereafter to be appointed "moderator."

THE SEEL INCANDESCENT LAMP FILAMENT.

From further information recently to hand we are able to give the following details of the manufacture of the Seel filament. The characteristic peculiarity seems to be that the incandescent threads are formed of three annular layers, of which the innermost is the real carbon thread. This thread is saturated with a solution of certain mineral salts and a gum, and is thus provided with a non-conducting coating of salt which melts during the carbonisation. This coating not only protects the carbon thread from burning during the carbonisation and excludes the air, but it also gives the carbon thread a smooth surface, on which the third layer, which is necessary for the adjustment of the resistance of the filament, is deposited in a uniform manner. The third layer is composed of carbon, precipitated by a certain process, in which a paraffin bath is used.

The method of preparing the threads is as follows:—Wood, silk, cotton, or any other vegetable fibre is steeped in a solution of mineral salts and a gum, consisting of a mixture of a silicate or salt, gum-senegal, and caustic soda, and then rolled firmly between warmed grooved rollers. It is rolled in the shape of angle-iron, in order to obtain a many-edged material of small diameter, so as to increase the illuminating effect.

When this operation is finished the thread is carbonised in the usual way. The carbonised thread is then placed in an insulated vessel and connected to the terminals of a source of current, in the circuit of which is placed a regulating resistance. The vessel containing the thread is then completely filled with paraffin or naphthalene, so that the thread is completely immersed and the paraffin allowed to harden. Current is then passed through the filament, which becomes hot, and the paraffin close to it becomes liquid, while that in immediate contact is even vaporised. In consequence of the heating, particles of carbon are deposited on the thread, and the resistance of the latter gradually decreases. The paraffin farthest removed from the charcoal threads remains solid and forms an envelope for those parts of the paraffin that are liquid, and thus limits the liquefying of the material as well as excluding the air. When the carbon thread has been lowered to the right degree of resistance the current is cut off and the thread is ready for use. The paraffin is then entirely liquefied by heat, so that the carbon thread can be drawn out. It is cleaned of the paraffin particles attached to it by means of benzine, and is then ready to be inserted

Digitized by Google

in the lamp. Hence the actual adjustment of the resistance of the carbon thread takes place in the bath, only the very smallest part of which is melted.

The advantage claimed for this method of treatment is that, owing to the presence of the gum-senegal, the pores of the thread are completely filled, and an exceedingly tough filament is obtained. The silicate and the caustic soda encompass the thread entirely, and when the latter is subjected to the rolling process they encircle it closely and uniformly on all sides. After being carbonised and prepared as described, the thread, therefore, consists of three layers, namely, the inner carbon layer, the annular silicate layer, and the uppermost precipitated, so-called "regulating layer," formed by the deposition of carbon.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The last meeting of this Society for the present Session was held on Thursday last, at the Institute of Civil Engineers, the President, Mr. Graves, C.E., being in the chair.

After the usual formal business had been transacted, Prof. SILVANUS THOMPSON delivered the following address upon

"Influence Machines, from 1788 to 1888."

Prof. THOMPSON: Mr. President and Gentlemen—On the 5th June, 1788, a letter was read at the Royal Society addressed by William Nicholson to Sir Joseph Banks, the then president. In that letter he announced his discovery, or, rather, invention, of an instrument which, by the turning of a winch, produces, in indefinite quantity, the two states of electricity, without friction and without communication with earth. The 5th June, 1888, will be next Tuesday; and, surely, we British electricians can hardly allow the 100th anniversary of the introduction of the influence machine to go by without at least recalling to our minds what has been done in that 100 years (hear, hear), and how from the simple beginnings of William Nicholson we have now the very perfect influence machines of to-day. But I may be allowed to go back a little earlier than 1788, because not only the influence machine, but the very fact that there is electrical influence at all, was discovered in England in 1753 by John Canton, of Stroud, in Gloucestershire, and we have, therefore, a double right to claim the invention of the influence machine, because of the discovery of the principle upon which it is based. John Canton's writings, which were mostly printed in the *Philosophical Transactions* of the Royal Society, are, to be sure, not altogether clear; he was an extremely clever man, and lived amongst his apparatus, working with it, becoming familiar with it, even as in a later time Faraday did, and his ideas grew up from the experiments he made, and took form in his own mind and were expressed in language that is not perhaps exactly that either of his own time or of the present time. One thing that Canton observed was that every electrified body was apparently surrounded with a sort of electrical atmosphere; and he gave a great deal of attention to this electric atmosphere, which he declared to surround all electrified bodies. Further experiments, really on the same point, though not expressed in the same language, were made by various experimenters. Franklin touched the subject very briefly. Wilcke, of Rostock, and Prof. Æpinus, then in Berlin, touched the subject from a somewhat different point of view. Æpinus in particular explained all the things that he observed, not by thinking of an atmosphere at all, but by introducing the mathematical notion of action at a distance, and he gave a certain mathematical theory to account for the facts that he observed. In Italy Jacopo Beccari, working on almost exactly the same problems, viewed them from a third standpoint, and discovered that a charge of electricity on a body behaves quite differently according to that which may be near it; that if you have a charged body—say, a glass plate rubbed on one side—and you bring something against the back of that plate, the charge on the front of the plate behaves differently, as though it were a large charge or a small charge, according to circumstances. To this peculiar action he gave the Latin name "*Vindex*." I do not know how we are to translate it. The "vindication" of electricity would not convey any intelligible meaning, I suppose, to our minds. That which Canton was referring to as an electrical atmosphere, that which Æpinus was referring to as an action at a distance, is that which Beccari was referring to by talking about electricity having a "vindicating" power, and it amounted simply to this—that in the neighbourhood of a charged body actions take place which are all explainable, which are all consistent with themselves, provided you will understand that the body which is brought into the neighbourhood of the charged body is acted upon in such a way as to tend to drive out of it electricity if the charged body has a positive charge, or to draw electricity from outside into it if the charged body is negatively charged. In fact, the action which we now call *influence*, and which for long was called *induction*, is nothing else than the action which all these various experimenters referred to. And, for my own part, I think that John Canton's notion of atmospheres was at least as useful as any of the other notions; it at least suggested that the intervening medium took an essential part in the phenomenon. Wilcke, in particular, made numerous researches, and in one of those he discovered the real, the true, principle of what we now call the electrophorus. Wilcke had a horizontal glass table. There is a drawing given in the *Proceedings* of the Swedish Academy relating to this; below that on an insulating stand there was a flat plate of paper covered with metal. Above the glass table there was another conducting plate suspended by insulating cords and a mechanism of pulleys to let it up and down. He discovered if the plate under the glass sheet were charged that the plate over the glass sheet separated from it by the glass could receive a charge, if it were lowered down on the table and were touched whilst it was there and then lifted up again. That discovery of Wilcke's was made in 1762, and some twelve years later Volta, in Italy, working again at the same kind of problem, investigating the apparent action at a distance, discovered the instrument which we all associate with his name, the so-called perpetual electrophorus. This in its modern form every one knows to consist of a cake of some electric substance which can be excited by rubbing it. He called it the cake, and a lid which Volta called the shield (*scudo*) which you place upon the cake so that it is under the influence of the charge. You touch it, then you take it up, and you find that it has a small charge upon it—a small charge, as a matter of fact, of the opposite sign. If your cake is of such a nature that its charge is negative when rubbed with the rubber, everyone knows as a most elementary fact that the charge which the metal acquires by being touched in its neighbourhood is a positive change. Volta further devised a condensing arrangement, which he used quite separately, but also in connection with his electrophorus. From that time there was great attention paid to this obscure fact of the existence of phenomena of influence. Probably if it had not been for the discovery of this simple and useful apparatus of Volta, not one-tenth part of the persons who immediately occupied themselves with experimenting on inductive action would have ever troubled their heads about it; but here was so simple an instrument that everyone could make it. I have put the names of those who followed in this list [Table I.]. The date, by the way, of Volta is given in the table as 1776; he really discovered the electrophorus a year or two before, about 1775; but he did not publish the discovery until some time after he had made it, and he went on experimenting, and his combination of an electrophorus with a condenser was used in 1778. One of those who followed after Volta, and who introduced a somewhat novel principle, was Lichtemberg, the same who discovered that peculiar kind of pattern or figure that can be obtained by sprinkling mixed powders, such as red lead and sulphur upon an electrified surface. Now Lichtemberg devised a double sort of electrophorus, and it is interesting, because it introduces the principle of reciprocal action. The electrophorus which Lichtemberg employed was made of wood, about 2ft. long and 1ft. broad, with a wooden rim nailed on, and a composition of resin, pitch, and turpentine cast into it. The way he employed it was this—he rubbed the plate near one end to excite it; having excited it, he placed the lid upon it, then he touched the lid, so that it acquired an opposite kind of charge, then having got it charged he made this communicate a portion of its charge to another part of the surface, either by putting the thing down edgeways, or by having a special discharging tool pointed at one end with a knob at the top, by means of which the charge could be "let off" on to the surface of the cake. Suppose you have a negative charge at the rubbed end of the plate; the charge obtained by touching the lid under influence would be a positive charge, and you now impart this charge to a spot at the other end. Now, then, having got a spot slightly positively charged, discharge your lid, put it down over the positive charge, touch it while under influence, and it comes up negatively charged.

TABLE I.

Canton	1753	Goodman	1841
Wilcke	1762	Svanberg	1846

Then discharge its negative charge on to the other end, discharge this, and repeat, and so carry from one end a positive charge to the other, and then use that positive charge to obtain a negative one. In fact, you will see that it is, to use the familiar language of the text-books, a kind of process in which you obtain charges by putting out your original charges at interest. You begin with a certain charge as your principal, you put that out to interest by the operation of touching the conductor whilst under influence, and every time you choose to perform this operation you carry away a fresh quantity of interest. But the curious point about this is, that when you have a surplus—when you have a positive charge as your principal, the interest is a negative quantity; and when you have a negative charge as your principal, the interest is positive—which is contrary to the ordinary way of the world (laughter).

However, that curious fact enables you to work reciprocally by having a sort of double electrophorus, and, taking the interest on the one, adding it to the principal of the other, and taking the interest on that and adding it to the principal at the other end. That reciprocal accumulative action is at the basis of all the modern influence machines. Almost at the same time Prof. Klinkoch, of Prague, invented an almost identical thing. The only difference from Lichtemberg was that he employed two separate cakes instead of one long cake. Then, from Lichtemberg, we come to another name,

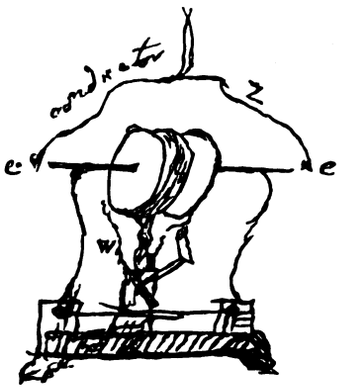

FIG. 1.—Facsimile of the sketch of the first Influence Machine by Erasmus Darwin, Esq., 1778,—recently recovered by Prof. Silvanus Thompson.

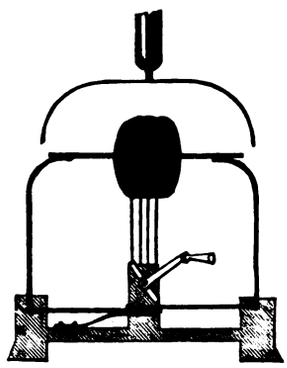

FIG. 2.—Probable appearance of Erasmus Darwin's Influence Machine.

a name which you will find mentioned in all the older cyclopædia articles in the history of electricity—I mean the name of Erasmus Darwin, the author of the "Botanic Garden," and the grandfather of the great Darwin (applause)—might I say the grandfather of the greater Darwin? Now Erasmus Darwin devised an apparatus for performing mechanically these operations of the electrophorus, by placing an insulated conductor under influence, touching it while under influence, and then carrying it away and making it give up its charge to something else. I searched vainly through all the literature of that time to try and find a picture or even an exact description of Erasmus Darwin's apparatus. It appeared to be a kind of *ignis fatuus*. The further one searched for Darwin's apparatus the more visionary did it become; and I was about giving it up in despair when I bethought me that there might remain possibly some unpublished literature on the subject. I had better read you first what is published. Darwin himself was greatly interested in the accounts of Volta's electrophorus, and in 1778, as we now know from unpublished manuscripts, he attempted to devise an arrangement for mechanically performing these manipulations. Bennet, one of the later experimenters, writing in a little book, "New Experiments in Electricity," published at Derby in 1789, says:—"Dr. Darwin, at the desire of Lord G. A. Cavendish, made the first attempts at such a mechanical arrangement with two plates moving between two others by a lever, so as to bring them to exactly the same position in each operation. This contrivance he soon improved by another instrument, in which the plates stood vertically and moved by rack-work in a direction exactly parallel to each other. This instrument was sent to Mr. Partington." I hunted in vain for Mr. Partington in all the cyclopædias and dictionaries. I then found a further reference in "Nicholson's Journal," dated 1797. It runs as follows:—"In the month of December, 1787, Mr. Partington lent me an instrument by Dr. Darwin, consisting of four metal plates, two of which were movable by wheel-work into positions which required them to be touched by the hand in order to produce these effects." That was the sum and substance of all that the cyclopædias could tell me. However, on applying to Mr. Horace Darwin, of Cambridge, he very kindly communicated with Mr. Reginald Darwin, of Buxton, and Mr. Reginald Darwin hunted up for me some old manuscripts of Erasmus Darwin's, and was successful in finding in a notebook of 1778 a page which has the drawing of this peculiar machine (applause). There is a rough facsimile upon the screen of this pencil sketch in Mr. Darwin's pages, and, below, a more polite version of the same apparatus (Figs. 1 and 2). In the middle there is a disc, which is electrified by rubbing, or has been electrified in some other way. In one case he used a metal sheet between two pieces of glass—the glass was to keep the metal sheet from sparking on to the other parts. Right and left of that there are two metal plates on insulating stands, worked by crank levers, and these crank levers move the plates towards the metal plate, and then move them away again. It is little more, you will see, than a mere mechanical translation of the action of placing a plate under the influence of a charged plate, and touching it while it is there. The more complex description of rack-work does not suit anything in this particular pencil sketch. However, the interest which Darwin took in this excited other persons; and Nicholson, having received from Mr. Partington this instrument, was incited to go further. In the

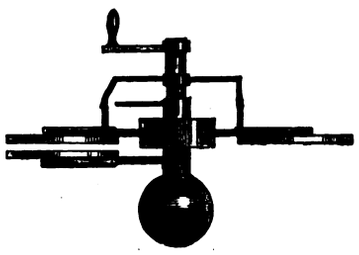

FIG. 3.—Nicholson's Doubler (plan view).

meantime, however, another small but very important piece of progress had been made. The Rev. Abraham Bennet was at that time curate of Wirksworth, and he communicated to the Royal Society, in 1787, a Paper under the following title, "An Account of a Doubler of Electricity, or a Machine by which the Least Conceivable Quantity of Positive or Negative Electricity may be Continually Doubled till it becomes Perceptible by Common Electrometers or Visible in Sparks." Now, Bennet's doubler was a very ingenious thing, though we can hardly call it an influence machine. It merely consists of three metal discs mounted with handles. I do not possess an actual specimen, but I have a rough model here lent me by Mr. Wimshurst, by which I may illustrate to you what is meant exactly by this doubler. Suppose this to be a metal plate, which I place on an insulating stand, and that it has a small charge of electricity somehow or other imparted to it. Call it 1. Now take a second metal plate and lay it close over it. The second one was varnished on both sides to prevent contact. Touch it while it is there by stretching out the forefinger. That plate will receive a charge which will not quite amount to 1, and will be of negative sign. If the first was plus 1, then the second will be minus 1. Then take the third plate, and place it over the second and touch it under influence. This charge will be not quite 1, but it will be 1 plus (nearly). Next take your plate into the plus 1 charge, lay it on the top of the third plate, whose charge is already plus 1, so that you obtain plus 2. From this you can immediately get minus 2 on your second plate. Now, then, over minus 2 lay the first plate, touch it, and you get plus 2, and having got plus 2, and put *that* down on the first plate, you get plus 3; and so you go on adding to the charge each time by these successive operations. Mathematically it is not exactly doubling, supposing the action to be perfect, but the meaning is sufficiently conveyed by the name "doubler." Now, Bennet's doubler at once invited the mechanical genius to step in and make it up into a working instrument, and that is exactly what was done within the next twelve months in two entirely different ways. The first way in which it was done was by Tiberius Cavallo, an Italian

Digitized by Google

physician, resident for many years in London. I have here an actual specimen of Cavallo's doubler. I may say that this is, to a certain extent, historical, for it is kindly lent to me from the collection of apparatus in the possession of the London Institution in Finsbury-circus. Cavallo's multiplier consists of four metal plates, three of which stand on insulating pillars, but the fourth, which is not insulated, is connected with the earth. Call them 1, 2, 3, and 4; 1 is fixed, 2 is movable, 3 is fixed, and 4 is close to it. No. 2 stands upon a lever, so that it can be moved horizontally from a position close to No. 1, into a position touching No. 3, and then back again. A small gap exists between 3 and 4 that can be increased, but should be as small as possible at starting. This acts as an air condenser. Now, supposing a small charge is given to plate No. 1; you bring plate No. 2 near to it, but not touching, but while it is there touch it. But Tiberius Cavallo gives you an apparatus for doing this. A wire comes down and touches an earth contact, so that it actually is touched while under influence. So it receives a negative charge, and goes on negatively charged until it gives up its charge to the plate on the other side, and as often as you shift this lever backwards and forwards the electrophorus action goes on; and in this way you multiply any very small charge. In fact, you perform mechanically a somewhat similar operation to that which Bennet proposed to use with the doubler (applause). There is, however, no accretion to the original small charge—the original small charge merely gives up interest every time. Cavallo made many experiments with multipliers and doublers. The thing, however, that bothered both him and Bennet was that, even though you imparted

Fig. 4.—Nicholson's Revolving Doubler (from an actual machine).

no charge whatever to the first plate to begin with, if your instrument was properly made and dry you always ended by getting a charge. Their difficulty was, not that the thing would not work, but that it would work when you began with nothing, or apparently nothing; and Cavallo made lots of experiments to find out how it was that these apparatuses appeared to work spontaneously, and he came to the conclusion that you could not possibly put two metal plates near to one another without their somehow or other acquiring different electric states. Further than that, I am afraid, he did not go; and his researches may be said to bring us to the end of the first period. Then, in 1788, as mentioned in my opening sentence, Wm. Nicholson devised the revolving or rotating doubler which we now associate with his name. I have here upon the wall a large drawing of Nicholson's revolving doubler (Fig. 3), and I have also here, lent me from the historical collection of the London Institution, a Nicholson doubler of ancient date (Fig. 4) I know not whether it be an actual century old, probably not, because it looks like an instrument maker's apparatus. Nicholson himself says that he only made one doubler, and that this was presented to Prof. Martinus Van Marum, who wrote a beautiful book on electricity, and who at that time was in charge of the Teylerian Museum at Haarlem. It might be worth while writing over to the authorities at Haarlem to know if that historic doubler is there. But here is the doubler lent us from the London Institution. It consists of two metal plates on the ends of insulating arms, and a third metal plate which goes first past one and then past the other. Supposing a small charge were imparted to either of these two plates, then the third plate, while it is opposite this, is touched—there is a spring that touches it. If, therefore, the first plate have any charge upon it, the moving one would receive a charge—an opposite one. Then that comes round, and will pass opposite the second fixed plate; this plate is touched by a wire that connects it to the ball, so that if that were positive the interest on it is negative. That comes round to the other side, and the interest of that will be positive, and will be communicated to the ball, which will be slightly positive. But when it comes round again to the other side another action also takes place. When the third plate comes opposite the first one, not only is it touched while under influence, but at that moment, by means of a rod, plate No. 1 and plate No. 3 are connected, so that any charge that remains in this, after having given up some to the ball, is joined at that moment to the charge in No. 1, and they act doubly upon the movable plate, and the movable plate is under the influence of a stronger electric charge than before; so that it receives a bigger interest, which is carried round to the other side. Thus, every turn of the doubler increases the charge on the original plate, so that turn after turn excites the machine more and more highly, until it has attained a certain state of excitation. I may say that I have a copy of the original Paper here, with a drawing of the doubler upon it. This instrument does not work very well, probably

Fig. 5.—Lecture Table Electroscope.

because the glass used at that time was not so good a glass as we nowadays employ.

[An experiment was then shown by means of a model of the apparatus which had been constructed by Mr. Wimshurst. This consisted of a large Nicholson doubler, one of the fixed plates of which was connected to a simple electroscope made of two lightly balanced leaves of thin wood, with paper discs at their upper ends (Fig. 5). This doubler produced, with about a dozen revolutions, a charge sufficient to cause the leaves to fly apart to a distance of four or five inches.]

Now, there is a very interesting effect I can show you. At the moment when the movable disc comes opposite the one to which this is connected it will of course exercise an action like that of a condenser while the interest is being taken, so to speak, by influence from the principal. If the charge on the fixed disc is positive, then when the movable plate comes opposite it, and is touched, it will be left negatively charged, and so the two charges being of opposite sign they attract one another across the space between: and, consequently, the free charge, part of which was upon the electroscope, is condensed back into the fixed plate of the doubler, causing the leaves of the electroscope to close together. But as soon as I bring the charged disc round to the other side the action is reversed, and the electroscope leaves open out again. Then we have here, in Nicholson's apparatus, an influence machine which can excite itself and which can increase its

Digitized by Google

own charges. The earliest criticism passed upon this machine by Prof. Robison was that, because the discs approached one another edgeways, you would have such a tendency to large surface-density at the edges that you would inevitably get a spark between the one and the other. That criticism is perfectly just, and in modern machines we find that—in general, at any rate—where you want to get any very high potentials, you do not have two surfaces of metal brought past one another without some kind of mechanical device, such as the introduction of a sheet of glass to prevent the possibility of a spark passing from one to the other. In fact, you must have at least *two* thicknesses of glass—one thickness is not enough—between the rotating part and the fixed part. One is not enough, for the simple reason that if you merely have one fixed or one moving sheet of glass, you have sparking or discharging in the air from the exposed metal part against the back of that glass, and the glass gets charged on its other surface with a charge which neutralises the effect of the charge on the metal conductor attached to it. You must have two thicknesses of glass. Now, from this point we enter upon the real history of the machine. In 1797 Nicholson devised what he called a *spinning condenser*. It is not quite clear from his account of it whether he devised it on his own notion or whether it was suggested to him by Bennet; at any rate, he says it was made after he had been talking to Bennet on the subject. In it there was a disc with two pieces of tinfoil attached to it, and this passed over a second disc which also had two pieces of tinfoil, one of which only was charged, and there were certain springs to touch so as to bring the charges round. In a very few years other forms had been devised. There was a Mr. John Read, who read a Paper at the Royal Society in 1794. His apparatus was like Nicholson's, but he called it a "spectacle doubler," because he made the discs of glass! You may judge of the strange sort of thing that Mr. Read brought

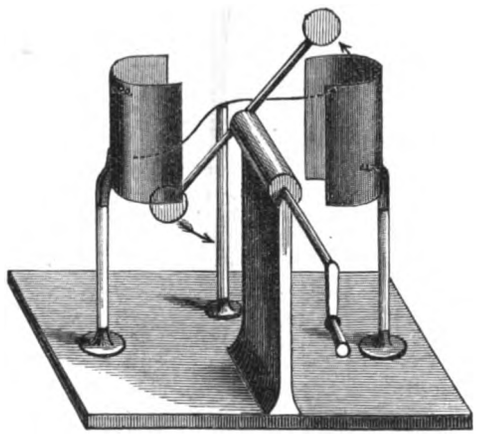

Fig. 6.—Belli's Doubler.

out with his doubler from this :—"Knightsbridge Charity School fills up a piece of ground between the north end of the chapel and Hyde Park wall, and the main sewer at that neighbourhood runs at no great depth under it. The number of children educated in this school is thought by some to be too great for the size of the school. On this account it becomes infected with a very disagreeable stench, especially when the doors and windows are shut up. I have sometimes found the noxious effluvium so very strong in this school that I have hastened out to breathe a purer air. I have often examined the electrical state of the air in this school with a doubler, and have always found it strongly negative" —and he made a number of unsavoury experiments in order to discover whether there was any real connection between the electrification which he could get out of a doubler and the atmosphere in which that doubler was worked. Then, to go on with my list, we come to a curious book, published in 1798 by a German pastor, Bohnenberger, which book is absolutely full of influence machines. Many of them are most curious machines. Some are made with mechanically sliding parts, some, like Cavallo's, with levers, some with rotating parts; in fact, there is one which is extremely like the Nicholson doubler set up on end. Doublers of various sorts grew and multiplied. In France Hachette and Desormes revived the Nicholson doubler, merely making an addition to the number of rotating parts. Then, about 1820 (the thing was not published till 1823, so I do not know the exact dates) the late Sir Francis Ronalds devised a form of doubler in which the movable plate was swung backwards and forwards at the end of a pendulum opposite the two fixed plates. In the case of Ronalds' doubler, as in Nicholson's, these two fixed plates were both to be charged with the same kind of electrification. If you began with positive electrification at one side the carrier became negative, but the plate at the other side became positive, and then these two were put together for an instant, so that any charge upon it might be used along with that in the further multiplying. But from the time of Ronalds onward, although we have two fixed parts and a rotating part, they are used not exactly in the same way; they are not both electrified with the same sign, but in the reciprocal manner devised by Lichtemberg in his long electrophorus. Henceforth, from this point onwards, when you have two fixed parts at the two sides, one is used as a positive and the other as a negative plate. As in the ordinary pattern of dynamo you have a rotating part between two fixed poles, so in the ordinary influence machine you have a rotating part between two fixed plates which I propose to call, and have for some time called, the "field-plates." Some people call them the armatures, some people call them the inductors; there are various names for these two fixed plates, but "field-plate" seems to me the name that is most comfortable to employ. As in the dynamo machine, we call that part which provides the magnetic field the "field-magnet," so in the influence machine I call by the name of "field-plate" that part which provides the electric field. Now, in 1831 Belli described a form of doubler which has this peculiar arrangement of two fixed field-plates, one of which has become positive at the same time that another one becomes negative (Fig. 6). In this case the field-plates are made of metal folded round on themselves, one at each side, and the two rotating parts are metal discs of about 1½in. diameter, carried at the ends of a glass stem. As these go round they are touched while under influence. You will see here at the back, standing also on an insulating stem, though it need not be insulated, a conductor. This has spring ends and extends down to the lower side of the field-plate on the one hand and to the upper part of the field-plate on the other hand. A little way down from the top of one field-plate and a little way up from the bottom of the other plate there are a couple of small springs soldered on inside, so that they touch these rotating carriers as they go round. Suppose, then, we start with a small charge, and one field-plate be slightly positive (the rotation is supposed to be left-handed in Belli's drawing), this little disc will go between the folds of the field-plate and be touched by the diagonal conductor

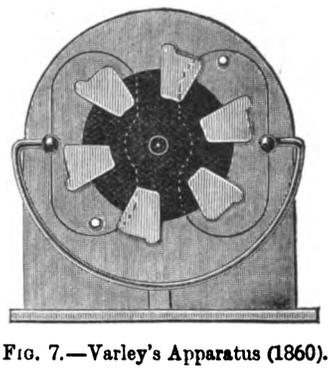

Fig. 7.—Varley's Apparatus (1860).

just the last thing before it comes out. It is then negatively charged while it passes round underneath; as it goes up on this side the first thing it does is touch the internal spring and give up its negative charge to the plate on this side. Then as it goes up the last thing that happens before it comes away from the negative field-plate is that it is touched by the contact spring on the other end of the diagonal conductor, and goes off positively charged, giving up its positive charge to the little spring on the inside of the other field-plates. Now that is absolutely typical of what happens in all the modern influence machines. Some time ago—in fact, long before I knew this particular apparatus of Belli's—for the purpose of illustrating lectures on this subject I devised an almost identical piece of apparatus, which I also have here, the only essential addition being the pair of discharging combs to receive any superfluity of charge remaining over. Curiously enough, almost an identical thing, though different in form, is the little replenisher which we have in Sir William Thomson's electrometers. All the essential features are present. There are two field-plates, right and left; there are two insulated pieces of metal on the ends of arms, which go round. I would like to call this rotating part with the two sectors on it an "armature." In the dynamo the part that rotates with the various sections or coils of wire upon it is the analogue of the part which in the influence machine rotates and carries around the metallic sectors or charged conductors. Each one of these metallic conductors being touched, while under influence, by a little brush goes off charged, gives up its charge to the other side, and so this thing charges itself up. Beside this doubler Belli devised another machine having a rotating plate of glass with metal plate affixed to it. To this machine he gave the name of *macchina ad attuazione*. I thought this must be a misprint for *attrazioni*—the *attraction* machine; but no, it is *attuazione*

Digitized by Google

in two places, and as the Italian dictionaries do not give that word I conclude that he made it up, and that it meant an actuation machine, a machine which works not by friction but by *actuating*, by being *actuated* or something of that kind; that is the nearest translation I can get for it. From the time of Belli there is a great gap; very little was done. There was a certain Mr. Goodman, of Birmingham, who made up a large machine which is supposed to work on the influence principle, though I am not at all sure that it does. Then Svanberg in 1846 devised another arrangement of a double electrophorus, where a disc had to be carried over the top from one electrophorus to the other. Then there comes a blank, and the science of the construction of influence machines absolutely died out, to be revived again by Varley. This brings us to the third period. In 1860 Cromwell Fleetwood Varley described an influence machine which had in it almost everything that we have in the modern ones, and, indeed, it is a machine of a very advanced type. In Varley's apparatus (Fig. 7) you have, as before, two field-plates; they were pieces of tin-foil stuck against glass—a large sheet of glass. They are those two oval patches in the figure. In front of them (or rather between them, for there are two sets one in front and one behind connected together) rotated an armature—a disc in fact—having carriers of metal upon it, which as they rotated were touched while opposite to one field-plate, and then went round to give up the charge so acquired to the other field-plate. Those two knobs which are joined together by a connecting arc are the parts which correspond to the neutralising brushes which touch the carriers as they go round. The knobs were used in some of Varley's actual machines, though he himself suggests that for certain purposes it would be better to use spring contacts. The rotations are in this figure supposed to be right handed.

(To be continued.)

THE ELECTRIC-LIGHTING SCHEME IN BRADFORD.

LOCAL GOVERNMENT INQUIRY.

On Thursday, May 31st, Major Tulloch, R.E., one of the inspectors of the Local Government Board, held an inquiry at the Town Hall, Bradford, in respect to the application of the Corporation for sanction to borrow £20,000 for the purposes of the proposed electric-lighting installation in the borough. There were only about half a dozen persons present in addition to the inspector. Alderman Frederick Priestman, chairman of the Gas Committee, and the Town Clerk (Mr. M'Gowen) represented the Corporation; and Mr. J. N. Shoolbred, electrical engineer to the Corporation, was also present.

The Town Clerk, in laying the case of the Corporation before the inspector, stated that some time since the Corporation obtained a confirmatory Act of Parliament which empowered them to supply electricity for lighting purposes and for motive power By that Act two years' grace was given to the Corporation, within which time they were to do something towards putting into operation the powers granted, subject to the condition that if the Corporation did not move within that period and any company wished to take up the project, the powers granted to the Corporation should not stand in the way. Before the two years expired, however, the Corporation introduced a Bill into Parliament containing clauses seeking to make their electric lighting powers permanent. The Board of Trade, after considering that portion of the Bill, came to the conclusion that it would be undesirable to give to the Corporation such powers in a permanent form, but gave them an assurance that if any other persons came to the borough with any project the Corporation should be duly considered, and the powers granted to them should remain in their hands unless there had been unreasonable and wilful default on their part. About that time, as the inspector would be aware, the subject of electric lighting was not so far advanced as it had since become, and it was thought best to let the matter remain in abeyance for awhile, pending such improvements as might be made. Some time afterwards a company came to the Corporation and asked for permission to carry cables over the streets. This seemed to the Corporation a most objectionable mode of procedure, considering the weight of the cables and consequent danger to the public; and as other persons, including the Post Office authorities, were required to carry wires underground in the busy part of the town, the Corporation refused the application. To some people it might have seemed ungracious on the part of the Corporation to refuse liberty to the company to use their electric powers while at the same time the Corporation had similar powers but neglected to carry them into effect. The Gas Committee thought it well to bring the subject up for discussion in the Council, and, it being found that there was likley to be a considerable demand for the electric light, it was, after full inquiry and consideration of the subject in all its bearings, determined that the Corporation should make a start. No one, however, yet knew sufficient of electric lighting to justify the setting up of a complete system for the whole borough, and it was thought that the most judicious mode of proceeding would be for the Corporation to select a central portion of the town, and to have a limited installation put down until it was seen how far the project was successful. Plans were therefore prepared by Mr. Shoolbred, acting for the Corporation, and it was resolved to seek powers to borrow the necessary money; and the Council having made application to the Local Government Board for that purpose, as directed by the Act of 1883, the result was the inquiry now being held. As the inspector well knew, the Corporation was required to give the utmost publicity to everything they did, and such had been the case in the present instance. So far as could be ascertained, the scheme seemed to meet with very general approval, and the absence of opposition was a strong testimony in favour of this view. It should be stated that the trade of the town was of a peculiar character, and the Corporation were told by the merchants that the electric light would be a great convenience to them, as facilitating the matching of tissues of the various textile fabrics produced in the town, as also in showing off the various shades of colour. It remained for the inspector to say whether he felt justified in recommending that sanction be given for the Corporation to borrow the amount for which application had been made. It was at first thought that £20,000 would be sufficient to meet the demands; but when tenders had been received for the necessary works it was found that nearly the whole of that sum would be absorbed, and the Corporation requested to be allowed to amend their application so as to include an additional £5,000. In the year 1871 the Corporation bought up the undertaking of an old gas company, and it might perhaps be thought that in seeking now to supply electricity they were cutting their own throats; but being satisfied that there was a demand for the electric light they wished to be able to supply it themselves, and so maintain the exclusive control of the streets, as they were apprehensive that if any trading company were to get a foothold in the town the difficulties of the Corporation would be very much enhanced. It was most desirable that only one authority should deal with the streets, and every arrangement would be made to secure economy in carrying out the project.

Alderman F. Priestman added his confirmation to the Town Clerk's statement, and explained the desirablility of having the works proceeded with as soon as practicable. Considering the substantial character of the plant to be laid down, he urged that the term of the loan should be as long as possible.

The Town Clerk proposed to call Mr. Shoolbred, the Corporation's electrical engineer; but the inspector stated that the engineer had already supplied him with the fullest particulars, and that no further information was really needed on his part, adding that there was nothing in relation to the scheme generally, or arising out of the inquiry, to which he saw the least objection. The inspector remarked that the best course for the Corporation to adopt would be to address to the Local Government Board a supplementary application for the additional £5,000 required. It was highly desirable that an inquiry should have been held, as the subject was new both to the Corporation and the Department. Indeed, he believed the Bradford Corporation were the first municipal authority to take action in the manner they proposed.

On the motion of Alderman Priestman, seconded by Mr. Joseph Edmondson, a vote of thanks was passed to the inspector for his courtesy in conducting the inquiry, and Major Tulloch having responded, the proceedings closed.

THE CONSTITUTION AND PLAN OF LICENSING ADOPTED BY THE "NEW ENGLAND ELECTRIC EXCHANGE."

The New England Electric Exchange is the title of an association which has recently been established in the United States for purposes which are fully explained by the following extracts from the "Constitution" of the new organisation:—

Article I.—The name of this association shall be the New England Electric Exchange.

Article II.—The object of the exchange shall be the general promotion of electrical business and especially in the direction of securing perfection in electric light and electric power installations, and in harmonising and adjusting so far as possible all differences which may arise between various electrical interests.

Article III.—Every one residing and doing business in the New England States and actually engaged in manufacturing or installing electric light or electric power apparatus, or in operating commercially an electric light or power plant, is eligible to membership in

Digitized by Google

the exchange, and may become members upon complying with the provisions of this constitution.

Article IV.—The officers of the exchange shall consist of a president, a secretary who shall also be treasurer, and a board of directors consisting of the above named officers and three other members, all of whom shall be elected by ballot at the annual meeting in April.

[After some formal clauses the articles proceed.]

Article V.—The directors shall be the governing body of the exchange; they shall meet from time to time, at the call of the president, or at the request of any two of their number, and shall adopt such measures for promoting the object of the exchange as they deem expedient, or as instructed by the exchange; they shall be the judges of the eligibility of all applicants for membership; they may fill until the next regular meeting of the exchange any vacancies occurring in their own body or in the offices of president, or secretary-treasurer.

Article VI.—Regular meetings of the exchange shall be held on the second Monday of April, July, October, and January, at such time and place as may be appointed by the president.

Article VII.—The annual dues shall be three dollars ($3.00) for each member, payable in advance, and shall cover the time between two annual meetings.

[The remaining articles are purely formal.]

PLAN OF LICENSING.

In order to promote ambition in excellence of workmanship and extent of knowledge among men practically engaged in installing or operating electric plants, and to thus make it an object for fire underwriters to recommend the introduction of electricity in preference to other means for producing artificial illumination and power, the New England Electric Exchange will issue licenses under the following general plan:—

Licenses shall be of five classes, each class representing a certain extent of qualification.

First class licenses shall be issued only to persons fully competent to instal and operate any electric light or electric power plant.

Second class licenses shall be issued only to persons fully competent to instal and operate any two of the following plants, viz., incandescent light, arc light, or power.

Third class licenses shall be issued only to persons fully competent to instal and operate any one of the following plants, viz., incandescent light, arc light, or power.

Fourth class licenses shall be issued only to persons fully competent to operate electric machinery, and who are not competent to do electric wiring.

Fifth class licenses shall be issued only to persons fully competent to do electric wiring and who are not competent to operate electric machinery.

Any person desiring a license shall make formal application to the secretary of the exchange specifying the class of license desired; these applications shall be referred by the secretary to the directors, who shall select three persons to examine the applicant and report upon his qualifications.

The examiners shall appoint, for the examination, such time and place as may be deemed by them advisable, and the applicant shall appear before them at such time and place for examination.

The examination shall be such as to satisfy the examiners as to the fitness of the applicant for either the license applied for or for one of another class.

All licenses shall be properly filled out with the class of the license, name and qualification of the licensee, certified to by the examiners, submitted to the New England Insurance Exchange or to the Boston Fire Underwriters' Union, as the case may be, bear in token of their approval the signature of one of their inspectors, and then be dated and issued under the seal of the exchange.

A license shall be valid for one year from its date, but the licensee may apply within that time for examination for a license of a higher class.

The directors of the exchange may, for cause, revoke any license granted by the exchange.

All applications for license must be accompanied by two dollars ($2.00) to help defray expenses, and must bear the signature of two members of the exchange.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 26th*, 1888.

We have just had given us in this city a remarkable evidence of the manner in which the march of improvement may be arrested by ignorance or corruption on the part of municipal authorities. The Harlem Railroad Company has been seeking for permission to change the Fourth and Maddison Avenue railroad into an electric road, using the Julien motor and storage system. Considerable preparations have been made for the work, of which I have already advised you, including the equipment of a very compact generating station, and the building of a number of remarkably fine cars. Public sentiment along the line is overwhelmingly in favour of the change, as shown by the fact that out of one thousand letters of inquiry on the subject addressed to residents on or near the avenue, 656 answers were received, and only five of those were against the scheme. All this had little weight with the aldermen, who by a vote of fourteen to ten this week have rejected the report of the railroad committee recommending the adoption of electricity. As may be imagined, some of the objections to the scheme were of an amusing nature, the chief opponent of the motor going so far as to assert that it would be dangerous for a passenger to have steel nails in his shoes. Another nineteenth century objection was that the introduction of electricity would throw thousands of workmen out of employment, just as though the total amount of labour to be done after all would not be the same; while the benefit and convenience to the public would be so great. The remarks made in the course of the discussion showed that however well informed the board might be about political machinery, it had plenty to learn in connection with that of an electrical kind. It is understood that the street railway company will run its cars as far down as 14th-street, and will await the development of public opinion to compel the aldermen to give it privileges below that line.

As a contrast to this, however, it is interesting and encouraging to note the reception given the Enos system at West St. Paul, Minn., operated by Thomson-Houston motors. In this system the car swings below the working mechanism, being carried practically on a one-legged structure, in which one rail stands above the other. The car runs about 14 feet from the ground, upon open and light truss work, and there is necessarily an absence of wooden guard timbers, cross tie-beams, sleepers, &c. The current is carried to the motor by the rails on the upper trestle, while the guide tracks or brake wheels follow the under trestle through the rail on which the return is made. A very successful demonstration of this system was made a few days ago, and was witnessed by the leading city authorities of the two great cities of St. Paul and Minneapolis, all of whom were greatly pleased with what they saw, and voted for electricity with both hands.

While on the subject of motors, I may mention that the Sprague Company, which has recently been paying special attention to mining apparatus, has brought out a mine hoist, which it has supplied to a corporation at Aspen College. This work is, as is well known, of a difficult character, and in the present case the electrical apparatus replaces a steam plant. There are to be two of these hoists put in, driven by 10 horse-power motors, while another motor of the same size is used for general miscellaneous service. The current is to be generated by water-power, and a circuit, a mile long, will be run from the turbines to the motors.

The Sawyer-Man Electric Company in this city is now rapidly settling down to work in its magnificent new quarters in West 23rd-street, where its floor space of 117,000 feet is ready for use. The Consolidated Company, using the Sawyer-Man system, has recently issued a broad-sheet circular, showing the number of installations and of lights under its patents. According to the grand totals given, there were on the 15th December, 1887, 308,302 lamps operating under the Sawyer-Man patents. On April 15th, 1888, there were 429,313, the increase in four months being 121,011 lights. The company proposes to give its factories combined a capacity of at least 10,000 incandescent lamps a day, a figure that furnishes some idea of its faith in the future of the business.

The prolonged telephone litigation seems now to have really reached its end in the refusal of the Supreme Court to grant a re-hearing of the Drawbaugh claims. I do not mean to say

Digitized by Google

that there will be no more Perkin Warbecks—in fact, there are one or two in the field now—but Mr. Bell has been held by the Courts now to be entitled absolutely to everything that he was granted, and all efforts to lessen the meaning of the broad interpretation given his patents must be hopeless. Of course, we have a good deal of newspaper talk about the iniquity of all this thing, and about the evils of the monopoly thus set up and fortified; but nobody seems anxious to impeach the Supreme Court, and there is, after all, even among those who do not love the Bell Company any too well, a feeling of satisfaction in seeing the value of patents so thoroughly established.

Quite a discussion is going on just now as to the cause of death by the electric current. Mr. P. B. Delany read a Paper last week before the American Institute of Electrical Engineers discussing the subject, and making a suggestion that a thorough investigation was in order. Prof. E. J. Houston has just published a Paper read by him before the American Philosophical Society, in which he expressed the opinion that death is due to electrolytic action of the tissue: to use his own words, in the case of the direct current death sometimes results from shock, but generally from the electrolytic effect on the blood or other tissues of the body; while death by the alternating current probably results from shock only. He explains the more frequent cases of resuscitation after shock from the alternating current by the absence of electrolytic decomposition of the tissues. In one of the electrical papers this week, Dr. Robert Amory in turn takes up the question, and refuses to allow Prof. Houston's explanations to go unchallenged. He makes the assertion that medical men are of the opinion that most generally death by electricity is caused rather by asphyxia than by chemico-physical effects on the living tissue. According to him, the animal functions of muscular contraction are thrown into strong tonic spasms, which will prevent the free respiratory movements essential to life. Hence the movement of the blood in the capillary circulation is arrested, the tissues are paralysed, oxidation of the blood ceases, the heart is no longer stimulated to action, and death ensues.

I noted recently in this correspondence the favourable remarks of one gas association president with regard to the electric light. These have now been seconded by President M'Millin, of the Western Gas Association. He submitted some interesting statistics in his annual address with regard to the manner in which electric light and power affected the gas industry. Taking the figures furnished by a number of gas companies, he found that the gas production had increased 7 per cent. during the year, while the electric lights had displaced gas burners that would have averaged a consumption amounting to about 10 per cent. more. The responses of the companies show that there was a marked increase in the use of electric lights over the previous year. From the information obtained, Mr. M'Millin drew various conclusions. One was that there was to be a struggle for supremacy between the gas engine and the electric motor, the latter being shown to have gained considerably. He thought that the struggle would result in the discarding of the small steam engines. He believed it also to be policy for gas men to supply electric light when possible, thus recognising the legitimate and reasonable demands of the public for a first-class commodity. Of the electric light he said that the time was coming when the public would demand arc or other powerful lights on most public streets. As to incandescent gas lighting, he said:—"It is making equal progress with the electric light; it is the most convenient, the most cleanly and the least objectionable from a sanitary point of any light now in use. Its convenience is making it popular. It will not do for gas managers to longer expect to fight it off by proclaiming its unreliability." This is striking language from a prominent gas engineer, and it does much credit to the speaker's clear perception of facts. It is perhaps not undeserving of note that a motion was made to change the name of the body to the "Western Gas and Electric Light Association." This was promptly vetoed down, but the mere fact that it was offered is very significant.

CORRESPONDENCE.

FIRE TELEGRAPHY AND FALSE ALARMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the leading article which appeared in your journal of the 25th of May on the subject of electrical fire alarms, and which criticises my Paper on fire telegraphy read at the Society of Telegraph-Engineers and Electricians, I was exceedingly pleased to find that you so fully support my conclusions that the aggregate destruction of property has been greatly reduced, notwithstanding the large increase in the number of fires, by the adoption of electrical alarms, and that this reduction may be extended in the future by the general employment of good systems of fire telegraphs, combined with a large number of street call-points.

Your straightforward criticism of so important a subject of public interest is sure to contribute largely to the desired object, and I accept willingly every word you have expressed, even when you accuse me of being "an enthusiast for fire telegraphy;" although I may be permitted to entertain some doubts as to the accuracy of this opinion. None can know better than the editor of an electrical journal what enormous difficulties are placed in the way of promoters of new appliances, however good they may be; hence a little enthusiasm is, perhaps, more a virtue than a vice. When once conservative prejudices are overcome and the ball is set rolling there is no further need for enthusiasm, and people will then begin to wonder why things were allowed to remain for so many years in this unfortunate state of "*Dolce far niente.*"

However, be that as it may, at present I am chiefly interested in considering the remarks made by Capt. Shaw during the discussion on my Paper. I must, in the first place, fully endorse your opinion that "the most valuable result of the Paper was the speech made upon it by Capt. Shaw, the chief of the London Fire Brigade," and "that we ought to give the carefullest attention to Capt. Shaw's remarks." I think the entire public ought to be grateful to that officer for having participated in the discussion, and for having given us information, hitherto unknown, of the greatest public interest and importance.

Capt. Shaw assured the meeting that the street fire-call points of London answer admirably, but that they are subject to the serious inconvenience of encouraging false alarms. The electrical calls transmitted from the London street call-posts during last year amounted to 362 false and 833 good electrical calls, counting in the latter, for my purpose, such calls as were sent unnecessarily, but in good faith, on mere suspicion of fire. It is this information concerning the large number of false alarms, coming as it does from so high an authority, which is very liable to cause misleading conclusions. The subject requires, therefore, as suggested in your article of the 25th May, some further investigation, the more so as this unfortunate experience connected with the London fire telegraphs is sure to act as a serious obstacle to the development of fire telegraphy in England if it be not at once shown that the serious inconvenience which Capt. Shaw's figures indicate need not exist.

Fortunately for fire telegraphy, however, it can easily be shown that Capt. Shaw's unfavourable experience is not the rule, but the exception. This I fully anticipated when the statement was made at the meeting; but not being prepared at the time with evidence to prove my belief I could only leave it for reply at a later date. Therefore, after collecting the necessary data, I communicated with your contemporary, the *Electrical Review*, and an article appeared on the 20th of April, making a comparison between false alarms sent in Berlin and in London, which clearly showed how considerably the high percentage of the latter could and should be reduced. In accordance with my table showing the number of false and good alarms during the year 1887 in London and in Berlin, it appears that in London 14·2 per cent. of false alarms were sent maliciously, against 3·5 per cent. in Berlin. Then, again, in comparing the fire-telegraph systems in the two cities from a technical point of view, the official figures show that whilst in 1887 London had 16·1 per cent. of false calls, inherent, in

one way or another, to the telegraph system in use, Berlin had not a single false alarm attributable to this cause.

The question of "false alarms" has thus, so to speak, a social and a technical side. The social question embraces the number of false alarms sent maliciously, whilst the technical question depends entirely upon the reliability of the telegraph system in use and of its careful installation. From what has been said already it is evident that the false alarms due to maliciousness are in London far too many, whilst those due to defects in the electrical system could, perhaps, be entirely eliminated by the adoption of a telegraph system which is intrinsically free from the defects which operate in causing the class of false alarms enumerated by Capt. Shaw.

In order to still further prove my views I have compiled the following table, which shows that the percentage of false calls sent from street call-posts in London is comparatively most unduly high, and that a considerable reduction is possible. I have been favoured with the statistics presented in this table by the chief officers of fire brigades in a number of towns on the Continent, chosen at random, but in all of which the Siemens fire-telegraph system is in use, a system with which I am personally acquainted.

It will be seen by a comparison between the results obtained in London and in these ten Continental towns that the technical question of false alarms can be satisfactorily solved, but with regard to the best means to reduce the present high rate in London of 14·2 per cent. of false calls sent maliciously, the only remedy is that suggested by Capt. Shaw, that the magistrates should punish severely anyone detected in interfering with the call-points. Similar annoyances by evil-disposed persons have been experienced in other services in their early days, but have almost entirely ceased in course of time. The former enormous malicious destruction of telegraph insulators is, for instance, still fresh in the memory of the older telegraph engineers, and the writer has a vivid recollection of a young man of fortune amusing himself persistently by shooting down in the morning the attractive glazed porcelain insulators, which had been erected the day before on one of the most important telegraph lines in the British Empire, specially constructed for the conveyance of news received from the seat of War in North America.

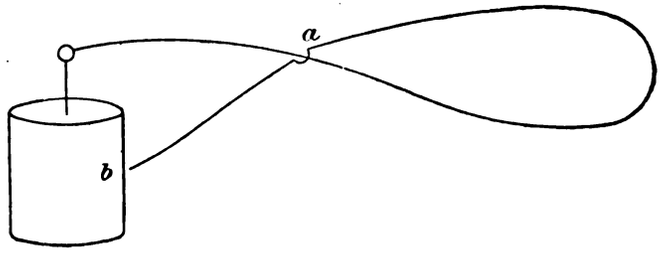
Lapse of time, the "properly administered" assistance of the magistrates and of the public in general, have acted so beneficially on the distorted minds of those few evil-disposed persons that, as our Post Office authorities could testify, a most desirable improvement has taken place in the preservation of the telegraph lines, and consequently of the service in general. I am therefore confident that with similar assistance on the part of the authorities the high percentage in London of 14·2 false calls sent maliciously will likewise in course of time become considerably reduced. Adding to this the adoption of fire-telegraph systems which are free from defects likely to cause false alarms there is no reason why false alarms should not become in London, if not entirely extinct, at least as rare as they are in many other large cities, which show an average of about 3 per cent. of false calls sent maliciously, and not more than about ½ per cent. due to defects in the telegraph system.—Yours, &c. R. von Fischer-Treuenfeld.

London, 2nd June, 1888.

ELECTRICAL OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your last issue I read with interest Mr. F. Higgins' letter. Let me say here that the curve given in my paper to assist in conveying a notion of the electrical oscillations at the establishment and rupture of a circuit conveying a current was in no sense intended as an accurate representation of the form of the current curve, but simply as a graphic device to avoid longer verbal description. It would be very useful if Mr. Higgins could give us the whole of his current curve up to complete steady current. As given in his Fig. 1 it seems to me to be only that part of the current curve which extends from zero to about half way up to the steady value. Any such actual observations, with the means by which they were obtained, would be most instructive.



Mr. Higgins deserves our thanks for drawing attention to the simple experiment with the two binding screws. Might I add that I do not recollect to have seen this same idea brought home sufficiently as an explanation of the *modus operandi* of a lightning protector on a telegraph circuit? The simple device of Mr. C. F. Varley of twisting together the silk or cotton covered wires leading from the terminals of the old single-needle instrument depended for its success as a lightning protector on the all but perfect opacity of the inductive circuit of the coils to sudden discharges; and the same is, of course, true of every other such device, such as the usual double-comb protector. All these are only forms of Faraday's old experiment of the Leyden jar discharged by a loop of wire, with the loop crossed in the middle and wires nearly touching.

If the discharge wire is crossed at *a* and nearly touches, then

Digitized by Google

on making contact at *b* the spark appears at *a*, even although there is a complete metallic circuit.

Following the nomenclature of dynamics, these brief electromotive forces producing electric discharges such as a spark, might be spoken of as *electromotive impulses*. The general result may be summed up by saying that if a network of conductors is submitted to an electromotive impulse, the course and sub-division of the discharge will be very different with very short discharges to that which it has when the discharges are relatively of much longer duration. Thus it would be highly probable (though I have never tried the experiment) that if a jar, as above shown, were discharged through a piece of wet string at *b*, that the dragging out of the discharge thereby caused would stop the spark at *a*, and make it take the course of the metallic loop.—Yours, &c.,

University College, London. J. A. FLEMING.

THE ELECTROLYSIS OF MERCURY BY THE ACTION OF AN ALTERNATING CURRENT OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Perhaps it will be of interest to some readers of your valuable paper to know of the peculiar behaviour of two mercury electrodes placed a short distance apart in dilute sulphuric acid when an alternating current of electricity is passed from one electrode to the other through the dilute sulphuric acid. As soon as a current is caused to flow, the mercury becomes agitated and presents a beautiful wavy appearance on its surface, which increases in its agitation as the current strength increases. The mercury at the same time being attacked by the acid forming an insoluble sulphate, this rises with the hydrogen which is liberated at the surface of the mercury in a cloudy form, and slowly falls to the bottom of the cell. This peculiar phenomenon is of great scientific interest, as this sulphate is formed in proportion to the current passing; consequently the mercury loses in weight in the same proportion. We made these discoveries in the course of an extended series of experiments to overcome the difficulty of metering alternating currents. Owing, however, to many mechanical difficulties in the use of mercury the idea to use this as a meter was abandoned. Further searches resulted in a successful issue, and we hope to shortly publish an account of the working of our meter.—Yours, &c. LOWRIE-HALL.

[Our correspondent has certainly made a very interesting discovery, and one which it would be extremely interesting to investigate further from the theoretical point of view. It can scarcely be correct, however, to speak of the "electrolysis" of an element.—ED. *E.*]

MR. HOWELL'S TESTS OF THE EFFICIENCY OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of May 4, 1888, you make the criticism upon a Paper read by Mr. J. W. Howell on "The Maximum Efficiency of Incandescent Lamps," that the method adopted for measuring the current in the difference of potential is the most important. This statement is supplemented with the hope that the instruments used were not of the ordinary "commercial" type. Your remarks imply that there is a probability that Mr. Howell, who is the electrician of the company, has not been supplied with proper apparatus for making determinations. To this we have only to say that for eight years the question of E.M.F. resistances and candle-power have been a constant study on the part of Mr. Howell, and that he has availed himself of every opportunity offered him to make comparison with the standards of other laboratories and firms. If he were to give an adequate statement of the precautions used to insure the accuracy of his measurements it would take a separate and equally long Paper as the one read. This was not deemed advisable. The difference of 1 per cent. in the volts in the marking of a sixteen candle-power lamp would make a difference of one candle-power in the light given. This makes the question of E.M.F. one of great importance in our business, and it has compelled us to have it under investigation continuously ever since we started business.—Yours, &c.,

(For THE EDISON LAMP COMPANY)
FRANCIS R. UPTON, Treasurer.

Harrison, N.J., May 22, 1888.

THE INVENTION OF THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. G. H. Staite's letter under the above heading in your last issue shows that he is labouring under a misapprehension as to well-known facts.

It is no doubt true that Mr. Edison's first patented invention relating to electric light by incandescence, though announced at the time as a great discovery, was, in fact, nothing more than Staite's invention adapted to the regulation of platinum incandescent lamps arranged in "series."

It may perhaps be of some satisfaction to Mr. G. H. Staite to learn that this invention, however ingenious in itself, is not the basis, nor indeed does it form any part of the system or systems of incandescent lighting at present in use, under whatever name they may be known.—Yours, &c.

ELECTRIC LIGHTING SCHEME AT EDINBURGH.

The Anglo-American Brush Electric Light Company have applied to the Town Council of Edinburgh for permission to equip a central lighting station, and draft conditions were adjusted by a sub-committee of the Council on the 30th ult. It is proposed to lay mains along Prince's-street, from Charlotte-street to the Register House. Several of the hotel keepers in Princes-street are desirous of introducing the light, and it is expected that about 2,000 incandescent lamps will be required. If the scheme is carried out the Callender-Webber system of underground electric conduits will be adopted, and the current will be charged for either by rental or meter rate. On Tuesday last the report of the Streets Committee came before the Town Council.

The TOWN CLERK proceeded to read the report as follows:—"Edinburgh, 30th May, 1888: At a meeting of the sub-committee of the Streets and Buildings Committee, on a letter from the secretary of the Anglo-American Brush Electric Light Corporation (Limited), asking permission to lay conductors in Rose-street-lane for distributing the electric current to hotels in Princes-street, the sub-committee, after consideration and examination of the plans submitted, agreed to recommend that the permission should be granted during the pleasure of the Council, and terminable on six months' notice by either party, on payment of 9d. per lineal yard per annum, payable quarterly, commencing the first payment on the —— day of September, 1888, when the said Electric Light Corporation shall pay 2¼d. per lineal yard for each lineal yard of street or ground broken or conductors laid, and so forth quarterly thereafter so long as this permission endures.

Bailie WALCOT said that the last clause about the 2¼d. was something he never heard of in committee.

The DEPUTY TOWN CLERK said it meant that the payment was to be made quarterly instead of yearly.

Bailie ROBERTS objected to the clause. He had never heard of it. They must keep by the committee's decision. He could not understand how the report had been altered.

The DEPUTY CLERK said the clause had been put in by Mr. Smith-Clark.

Bailie ROBERTS said that he did not think it was proper that the report should have been altered.

The clause was then struck out.

Bailie WALCOT said he had wished the report read, to show that they had not given the Brush Company any exclusive right.

Mr. MACPHERSON said there was no use talking about the Company laying the pipes in three months; three years was more like it. He agreed that the report should have come to the Council as it left the Committee.

Mr. MILLER DUNLOP objected to giving such powers to a private company. There was an understanding that they were to keep the electric lighting in their own hands.

Mr. KINLOCH ANDERSON said that was true, but this was only an experiment, and even if it succeeded the Council could take up the electric light if it was becoming general.

Bailie WALCOT moved the adoption of the report, and said there was a strong conviction in the committee that it would be an improper thing for them to throw any obstacles in the way of the progress of electricity. He believed there was a great future for both gas and electricity.

The DEAN OF GUILD said that was all right, but were they to allow this or any other company to tear up their streets?

Bailie WALCOT said that was included in the charge. Perhaps they had better hear the report as amended.

Digitized by Google

The TOWN CLERK again commenced to read the report:—Agree to recommend that permission should be granted during the pleasure of the Council, and terminable on six months' notice by either party, on payment of 9d. per lineal yard per annum so long as this permission endures—

Bailie M'LACHLAN (breaking in): It ought to be added that 9d. per annum is the minimum charge.

The DEAN OF GUILD: That is not the point. It is the grammar of it (laughter).

The LORD PROVOST: Better re-commit it.

Bailie WALCOT: Perhaps you will hear it all read.

The TOWN CLERK then read the rest of the report, which was as follows:—

"The work to be executed to be carried out within six months from this date at the sight and to the satisfaction of the committee and of the city road surveyor, under plans and specifications to be submitted by the promoters; the portions of streets to be passed through to be lifted, relaid, and maintained by the promoters to the satisfaction of the city road surveyor, and restored in the same manner in the event of discontinuance of the permission by the Council, or of the promoters ceasing to exercise their rights under said permission; the arrangement being also on condition that said Electric Corporation shall in no way interfere with gas, water, or other pipes or drains. The sub-committee are treating this as merely an experiment, and to be understood as such, leaving it open to revise the foregoing conditions at pleasure. Further, the said Electric Corporation shall not on any occasion or for any purpose interfere with the pipe track, or with the streets or lanes through which it passes, without warrant by the Town Clerk." The report was signed George Roberts.

"1st June, 1883.—The Streets and Buildings Committee approved of their sub-committee's report, and begged to recommend the Magistrates and Council accordingly. (Signed) G. R.

Mr. MILLER DUNLOP said the Brush Company could go over the whole city on that agreement.

The TOWN CLERK said the plan showed what streets were meant.

Mr. MILLER DUNLOP said they ought to have been specified.

Bailie ROBERTS seconded Bailie Walcot's motion.

Bailie WALCOT said he did not think the report made it clear that the Brush Company had not got an exclusive right here. Let them understand that any other company could get the same right as themselves.

The DEPUTY CLERK: You could not give them an exclusive right if you tried.

The LORD PROVOST said it would be wiser to re-commit the matter. He must say that he did not think documents of that sort should be left to one member of the committee to revise. They ought to be completed before they left the committee's hands.

Bailie ROBERTS said the report was completed. But, of course, Mr. Smith Clark and Mr. Harris went to the window and talked the matter over there, and they seemed to have put in the few words which were objected to. But the words were deleted, and it was all right now.

It was then agreed that the matter should be re-committed.

AN EXPLANATION.—In reference to the electric light minute given above, Mr. Smith Clark, who had left the Council meeting before the matter came on, upon reading the report of what occurred in the evening paper, made the following explanation:—The draft minute which was submitted by the Deputy Town Clerk to the Committee on Friday last, 1st inst., was regarded as defective in several respects. It was, however, approved of, subject to such alterations as might be made upon it by Mr. Smith Clark, who was requested by the committee to revise it. Mr. Clark, upon revisal, found that, while the minute stipulated for an annual rent of 9d. per lineal yard, it contained no provisions as to when the rent should commence to be payable. He accordingly inserted a stipulation that it should be payable quarterly at the rate of 2¼d. per lineal yard. On the same day (1st inst.) Mr. Smith Clark sent the draft minute to the Deputy Town Clerk revised, accompanied by a letter requesting the clerk to show his alterations to the convener, Bailie Roberts, for his approval. He added that the provisions as to payment of rent were important, and had been inserted so as to avoid any future question; and that as these alterations were intended merely as suggestions, the Deputy Clerk might make any corrections upon them, subject to the approval of Bailie Roberts. Apparently neither Mr. Smith Clark's letter nor his alterations had been shown to the convener of committee.

PARLIAMENTARY INTELLIGENCE.

ELECTRIC LIGHTING ACT AMENDMENT BILL.

In the House of Commons on May 31st, on the Committee Stage of the Electric Lighting Act (1882) Amendment Bill,

Sir G. CAMPBELL moved the addition of the following words to the first clause:—"When a local authority duly applies for a license for an area within its jurisdiction such license shall be granted by the Board of Trade unless the Board of Trade are of opinion that special reasons exist why such license should not be granted, and in such case they shall make a special report stating the grounds of their refusal. The grant of a license to any company or person shall not in any way hinder or restrict the granting of a license to the local authority, or to any other company or person, with the consent of the local authority within the same area."

Sir M. H. BEACH said that he was willing, on behalf of the Government, to accept the Bill as it stood, but could not agree to the proposals in the amendment. If the amendment were pressed, he should feel bound to object to the matter going any further.

Mr. MUNDELLA condemned the amendment as being absolutely unnecessary and mischievous, and hoped that it would be withdrawn.

Sir G. CAMPBELL said that when he was told this clause was mischievous he began to think there was something in it (laughter). He declined to withdraw the amendment.

Mr. BIGGAR moved to report progress, and the motion was carried.

NEW COMPANIES REGISTERED.

THE "ELECTRICIAN" PRINTING AND PUBLISHING COMPANY, LIMITED.—This Company is registered with a capital of £10,000, in £10 shares. The subscribers are:—

Sir John Pender, 18, Arlington-street, Piccadilly, K.C.M.G.
Sir James Anderson, 62, Queen's-gate, Knight.
Louis Floersheim, 4, Bank-buildings, E.C., Merchant.
John Denison Pender, 51, Hans-place, W., Gentleman.
Louis Schott, 4, Bank-buildings, E.C., Merchant.
James Pender, Thornby Hall, near Rugby, Gentleman.
K. L. M. Anderson, 10, Throgmorton-avenue, E.C., Stockbroker.

COMPANIES' MEETINGS & REPORTS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The seventh annual general meeting of this Company was held at the Cannon-street Hotel yesterday, Thursday, under the presidency of Mr. C. L. W. Fitzgerald.

The SECRETARY (Mr. Charles Curtoys) read the notice convening the meeting, and the report of the Directors (given below) was taken as read:—

The CHAIRMAN said that the amount available as the profit of the year was £10,788, which with the balance brought forward was increased to £12,484. They had already paid an interim dividend at the rate of 5 per cent. per annum, and they now proposed to write off the machinery, plant and furniture £541; and pursuing the policy which they had always carried out, of writing down the value of things, they proposed to write off the further sum of £2,000 from the item of investments in telephone companies—that was, from the investment in the Edison-Gower-Bell Telephone Company. That investment had now been written down from £25,000 to £18,000. The ordinary expenses of the year had been, in round figures, about £200 less than those of the previous year. In going through the accounts and balance-sheet he stated that the plant to-day was in a most efficient state, and they had gone on improving it, while they were reducing its value. The stock of instruments was about £1,000 more, which was caused by their taking over the stores of their late contractor. The sum on the debit side of the balance-sheet of sundry creditors and credit balances was now pretty well paid off. He believed they only had practically about £300. They now proposed to pay a further dividend of £2. 17s. per cent., which would make a total dividend for the year of £5 7s. per cent. Col. Gouraud's action against the Company for payment of his fees for the year 1883–4 had been decided in that gentleman's favour, and he had now, after nearly four years, commenced an action against the Committee of Investigation on the ground that the reports published to the shareholders were libels upon him. The Directors were advised by the solicitor that the reports were privileged reports, and all he could say as Chairman of the Committee was that nothing could have been further from their thoughts than the idea of libelling Colonel Gouraud. There was no object in doing so. What they did try to do was to show to the shareholders what they found from the minutes, and they put that in print. Whether Colonel Gouraud would proceed with his action he could not tell. The Edison-Gower-Bell business in Portugal had been sold to a company called the Anglo-Portuguese Telephone Company, which had already issued one report, which was decidedly favourable. Since they had taken the manufacture of telephones into their own hands, he had mastered their manufacture sufficiently to be able to say that he could undertake the management of the business. Since they had been working—since the contract was terminated—everything had gone on satisfactorily, and they ought to make more profit than if they employed a third party who contracted to make the instruments at a fixed price. He was sure that the shareholders would be glad to hear that all the telephone companies were working in harmony together, and no doubt, should the amalgamation scheme take place, of which he thought there was every probability, they would see a very considerable advancement in the number of telephones ordered; for this reason, that he thought every one could understand that provided they could talk from London to Manchester, Liverpool and Leeds, there would be many people who would take telephones who would not otherwise have them. He believed the fusion was extremely probable, and it would be a very good thing for all of them, and would make them much stronger in regard to their relations with the Government. One of the most satisfactory features in the whole report was the progress of the subsidiary companies. The Telephone Company of Austria increased by 245 subscribers, and in income £1,801; and the Anglo-Portuguese Company—the late Edison-Gower-Bell Company—had increased by 130 subscribers, with an income of £994. He had been looking over the figures of those companies from the year 1884, when he saw that the Telephone Company of Austria had 626 subscribers, and an income of £4,227, while the Edison-Gower-Bell subscribers

Digitized by Google

numbered 603, with an income of £4,000, making a total of 1,239 subscribers, and an income of £8,227. Those totals were now as follows :—Subscribers in Austria and Portugal, 3,536 ; and income, £23,255. Further than that, they had at last made those companies absolute money paying concerns—in other words, he and his friends on the Board had found the money for those companies, so that they should have working capital, which they never had before, and they were now paying cheques to the Company for the goods made for them. Having referred with satisfaction to the acquisition of Mr. Buckingham on the Board, he concluded by moving

"That the statement of accounts and balance-sheet and the report of the Directors and auditors, as now submitted to the meeting, be received and adopted, and that a final dividend of £2. 17s. per cent. be paid, making, with the interim dividend previously paid, £5. 7s. per cent. for the year ended 31st March, 1888."

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the motion, which, after a short discussion, was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. RICHARD VAN ZELLER, Sir Alexander Armstrong and Mr. Arthur Henry Baker were severally re-elected to their seats at the Board ; and subsequently the auditors, Mr. J. G. Griffiths and Mr. A. E. Green, were reappointed auditors.

An extraordinary general meeting of the Company was afterwards held, when, on the motion of the Chairman, seconded by Mr. Grëwing, a resolution was passed in effect terminating the management by the Company of the business carried on by it in Austria for the Telephone Company of Austria (Limited).

On the the motion of Mr. WARD, seconded by Mr. GERMAINE, a vote of thanks was passed to the Chairman and Directors, and the proceedings terminated.

[A full report of the meeting will be published next week.]

The accounts of the operations of the Consolidated Telephone Construction and Maintenance Company for the year ended 31st of March, 1888, show a net profit of £10,788. 7s. 4d., which, with the amount carried forward from last year, leaves a balance of £12,484. 5s. 9d. for disposal, after making provision for doubtful debts.

The Directors propose to deal with this amount as follows, viz. :—To pay a further dividend of £2. 17s. per cent., making with the interim dividend paid in November last £5. 7s. per cent. for the year, writing off the sum of £541. 6s. 3d. for depreciation of plant, machinery, and furniture, and the sum of £2,000 from the Edison Gower-Bell Telephone Company's securities, thus leaving a balance of £1,372. 9s. 11d. to carry forward.

The Directors have received a further sum of £4,427. 14s. 5d. on account of profit arising from the liquidation of the River Plate business, which is included in the above statement, and there is still a further considerable amount to be received under that head.

They have received an interim dividend at the rate of 5 per cent. on the shares of the United River Plate Telephone Company, which is also included in the foregoing.

The action brought against your Company by Colonel G. E. Gouraud for the payment of his fees for the year 1883-84, at the rate of £1,000 a year, was decided in his favour. He has now, after waiting four years, thought fit to commence an action for libel against the Committee of Investigation appointed by the shareholders in May, 1884, on the ground that the reports are personal libels.

Colonel Gouraud's action against your Directors for the course they have pursued in conjunction with the Edison Gower-Bell Telephone Company in prosecuting infringers of their patents in Belgium has been again postponed at his request. So far as the action in Belgium is concerned all has gone favourably, and the case has arrived at the stage when experts will be called to decide if an infringement has been committed.

The negotiations in Portugal alluded to in the last report have been satisfactorily terminated, and the result is that a very favourable concession for the working of the telephone business in the cities of Lisbon and Oporto has been granted to the Anglo-Portuguese Telephone Company, to whom the Edison Gower-Bell Telephone Company sold the Portuguese Exchange business for 37,500 fully paid £1 shares in the new undertaking.

Your Directors have deemed it necessary to terminate the contract which they had for the manufacture of telephones, &c., and to take the management of the factory entirely in their own hands. This was accomplished in February last, since which time all has been working smoothly and satisfactorily. Under the agreement with the contractor your Company had to purchase a certain amount of material and stores, which explains the increase of stock shown in the accounts.

The Directors have pleasure in stating that they are working in complete accord with the United Telephone Company, from whom they are expecting large orders, seeing that the development of that Company is progressing very favourably.

A fusion of all the Telephone Companies of the United Kingdom being in contemplation, your Directors are using their best endeavours to promote your interests in connection with the same.

The business of the subsidiary companies continues to make most satisfactory progress.

It is with extreme pleasure that your Directors have to announce that Mr. J. H. Buckingham has joined the Board.

In accordance with the Articles of Association the following Directors retire by rotation, and being eligible, offer themselves for re-election, viz. :—Sir Alexander Armstrong, K.C.B., &c., and Arthur Henry Baker, Esq.

The auditors, J. G. Griffiths, Esq., F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and A. E. Green, Esq., F.S.A.A., also retire, and offer themselves for re-election.

Swan United Electric Light Company (Limited).

An extraordinary general meeting was held on Tuesday at the Cannon-street Hotel for the purpose of considering and, if deemed desirable, of approving of an agreement dated May 5, 1888, made between this Company and the Compagnie Continentale Edison de Paris, and for authorising the Directors to do all acts necessary for carrying such agreement into effect.

Mr. JAMES STAATS FORBES occupied the chair and said :—Gentlemen, this is a very important meeting for the shareholders of this Company. I will try to be as brief as possible, but, in view of the great importance and perplexity of the matter, I am afraid I shall not be very short, because I think it necessary you should understand what you are about to do. What we are about to do is, in fact, to imitate abroad what we have done with great advantage to ourselves at home. You know the history of the United Company, in which you have a very large interest. You were in litigation with the Edison Company as to the respective patents of Mr. Swan and Mr. Edison in Great Britain and Ireland. We took very strong views of the priority and value of the Swan patents, they took the same views as to the priority and value of the Edison patents, and we were fast verging upon what might possibly have been ruin to both companies—litigation to the death to settle which was the governing patent and whether there was any patent at all. In that state of things, happily for us, prudent counsels prevailed ; the two companies were put together on the theory of making the best of what had been done, assuming *bona fides* on both sides, in building up the united business, which should have the advantage of preventing litigation, the raising of very delicate questions as to the value or priority of both sets of patents by uniting them both, for the purpose of defence against the common enemy, the infringer. Now, that is what we did in England ; it was rather more easy here, for the reason that the Edison Company had got the entire control of Edison's patents in Great Britain, and the Swan Company had got the entire control of the Swan patents. There were no other interests ; but abroad it is a little different. There, as here, Mr. Swan and Mr. Edison are face to face, as here the one accuses the other of infringement ; the Swan Company abroad are in the same position as they were here—that is to say, wherever patents have been registered they are the sole possessors. That it not quite the case with the Edison ; they seem to have been handed over originally to one or more parties by Mr. Edison, and as we have to deal with things as we find them, it is not much good going into their history. We find, however, that the Edison Company of Paris, with whom we are dealing, have not the same absolute power over the patents for the whole of Europe that the Swan Company has, or that the Edison Company had in Great Britain. You will see at once that led to rather more difficulty in negotiations. There have been more Richmonds in the field. The Swan Company for the last two years have been not indisposed, in view of the legal proceedings on patents, to come to an agreement with the Edison Company abroad ; but we were face to face with considerable internal difficulties, in fact to know who we were to negotiate with, and how one district was to be protected in which one set of people had the command, and another in which another set of people had the command. That has taken a great deal of time, and we have come to the conviction that it was wise to do abroad what it was wise to do here, for the very same reasons. While conflicts were going on, there was great uncertainty and cost in fighting. In the second place, the fact of there being litigation has a depressing effect on the spread of invention. People do not like to go into installations and run risks of being served with notices from time to time that they may be preparing for themselves the defence of an infringement suit. The object, therefore, was to put these companies together. The object and the reasons were generally what I have stated—for the purpose of mutual protection, advantage, and defence, because in every place in Europe there are lots of clever fellows who will make and sell lamps on the patents of Mr. Edison and Mr. Swan and pocket the benefits if we let them. Now we shall be much stronger and united against infringers by having both sets of patents under our control ; and, besides, in a place in which one patent may be weak, in another it may be strong. We then come to the delicate point in all such negotiations—the relative value. It is very difficult to find out and appreciate the relative value of what is partially unknown, because although we have heard of the Swan and the Edison lamps for a good many years the business is still, so to speak, in its infancy. It is a great undeveloped business, and the development of that business would depend very much, if we remained distinct companies, upon who won the suits. If the result of that litigation was to bar the Swan Company from manufacturing lamps all over Europe, and to give the Edison Company, so to speak, the monopoly of that manufacture, the relative portions or values would be greatly altered. Those questions have never been brought to issue. We have had to resort to the only known factor which influences men's minds in the circumstances—that is, having both gone on the theory that the patents were valid patents, we have each done a business, we have each a going concern, the businesses have been founded on different principles ; we for instance have paid cash for our patents, the other people have bound themselves to pay royalties on their patents. We have spent a great deal of money in these foreign countries in bringing our business to its present standard of expansion. Well, we have gone on the simple factor, how much work had we done, how many lamps had we manufactured and sold ? That seemed to be one reasonable factor. That had to be modified by some considerations ; for instance, if these suits which are pending in different countries, in Germany, in France, in Austria, and in Belgium, if they should go absolutely against one company or the other, that would be a very disturbing factor, or if the result was to throw these patents open to all the world we should both be in a bad state. Many people would hesitate to attack a united company, but none would if the result of the action of the two companies was to proclaim to the world that

Digitized by Google

the patents were not binding, and were open to all. We have taken similar views on both sides of the relative value of that factor. Fortunately, the method of computing the proportion does not involve the necessity of dealing with the capital of either company. In going into the question of what it has cost A or B we have taken the factor of the business actually done as the basis of the future division of the profits of the business. The thing was to get rid of this litigation, and to proceed as a united company to extend the business. The administration costs will probably be somewhat diminished, the efficiency of the lamp will be greatly improved, the public mind will be set at rest, there will be no alarming forebodings that people may be challenged as infringers and subject to legal proceedings, the business will increase, with the increase of numbers the profit on lamps will greatly increase. This is one of those businesses where a comparatively small number of lamps means a profit inconsiderable in comparison with a much larger output. The charges are comparatively great on the small quantities, and are greatly diminished on the increased output. Supposing on an output of a quarter of a million you make 1s. a lamp, if you increase the ontput to half a million the profit may be 1s. 6d. What we think is that our plan of putting these companies together will effect a double object, not only increase the output, but it will reduce the cost of each individual lamp, so that the profit will be greater. In order to express in legal language what I have told you in so few words it has been necessary to enter into an agreement with this Continental Company of Paris, and I had better perhaps briefly, before submitting the agreement to you, for your information go through the different articles so that you can understand exactly what it is. It is to be a union of the two companies; it is to be called the Company General of Incandescent Lamps; the duration of the company is to be fixed by the statutes up to the 31st December, 1894, that being, in fact, about the day or a little beyond the day when the patents of both Edison and Swan lamps die; it is a few weeks in case of the necessity of winding up the companies. In that event there would be time to do it; but that term may be prolonged or reduced, if the necessity should arise, by the resolution of a special meeting called for the purpose, but only when such resolution is passed by a majority of three-fourths of the share capital of the Company. I cannot myself see any reason to believe that, during the term of the patents at all events, there will be any necessity to interfere with this as a going concern. I think it is exceedingly likely that if the business is managed with tolerable prudence, that at the end of the six years you will have a well-established going concern, not protected by patents, which then will be thrown open to all the world, but probably protected by improved processes, which in the interval may be patented; at all events, if not that, by a large connection all over Europe, and by a trade mark which I hope will have behind it the character of the most efficient and best incandescent lamp which can then be produced. If that be so, this Company would go on; it would go on, I suppose, on conditions which we need not even anticipate now, but I should think, possibly, very much on the conditions of this agreement. I must tell you that this is to be a French Company, that is to say, a Société Anonyme, which is equivalent to our limited liability. The seat of the Company will be in Paris, but may be transferred to any other place. What do the parties bring in? This is an arrangement based on bringing in a going concern, or rather two going concerns; we propose to bring in what we have got, and they propose to bring in what they have got. What they would bring in is France, Belgium, Austria, Hungary, and Spain, that is where the Edison patents are under the control of this Company; we bring in France, Belgium, Russia, Austria, Hungary, Italy, Sweden, Norway, and Portugal. There is one important area entirely left out, that is Germany. The gentlemen in Paris have not the power of controlling the Edison interest in Germany, and, as I have had occasion to tell you at some of our meetings, in Germany, amongst other places, we are in litigation. But it is not impossible, when this preliminary step has been taken, Germany may follow. However, Germany is excluded from this agreement, the reason being that they cannot bring in Germany. There is one point of importance which I should be very glad to make clear. I said that this business had been founded on different principles; whereas we out and out bought the Swan patents by shares and money, the foreign people submitted themselves to a tax or license—or royalty, I think, is the proper term—of twenty centimes a lamp. That has been one of our great bones of contention and difficulties—these twenty centimes. Well, it is the payment made to Mr. Edison for bringing in his brains and patents. In France he got a royalty of somewhat under twopence on all the lamps manufactured within the area of these patents. We have had to look at that, amongst other things, and we have seen fit—I do not know that I need enter too largely into the discussion of why, as a matter of prudence and after full consideration—to accept that twenty centimes as a charge on the old business, but only for the duration of the patents. Now, that is one of the points which made us insist so strongly upon each party bearing its own burden. The contract was that twenty centimes should be paid as long as the Company existed; we have agreed that it shall be paid till the end of the patents. I have told you what everybody brings in, and the consideration for bringing it in is the creation of a certain quantity of shares, representing what has been done heretofore—what I may call the cost of the affair up to date—and a further amount of shares representing the capital which it will be necessary to find to develop this business from time to time. Now, it is not a big thing; you need not be alarmed by supposing you have immediately to find more capital. The share capital of the Company is to be 2,000,000fr., which is £80,000, of which 1,000,000 is to represent in fully paid shares the values of the going concern as put into the common pot, and the other million is to be made up of cash contributed by the companies in the respective proportions in which the profits of the united concern are to be divided. The division of these profits was a very anxious matter, and I think you may give us credit for having been ourselves largely interested—not that I think the mere pocket influence is the full consideration which ought to bind honourable men acting in the control of others, but still it has a certain interest; but being, first of all, large shareholders, and, what is more, being the implicitly trusted Directors of this Company, we made the hardest possible fight about the proportion, and I think Mr. Leyland, who has taken an immense deal of pains over this matter, will agree with me that we have reason to be very well satisfied with the proportions brought out. We think that, looking at the relative work done by the two companies; looking at the risks of litigation in these different countries; looking at the position which these people have got into in France, Belgium, and Austria by combinations which they have made with important people, that they stood upon the very nature of the thing to do a bigger business than we did. That is to say that their chances, if we had gone on even in a friendly way, were of a character to give them a better business than ours. Then there was the great risk of our failing on these patents, and that was a very serious matter, so that altogether the Directors are quite satisfied and are prepared to take all the responsibility of recommending you to accept the proportions. I have told you what the respective proportions of the companies are to be in consideration for their contributions. There shall be allotted to the Continental Company 1,200 shares, and to the Swan Company 800, of 500fr. each, fully paid up. That represents the million of francs which I told you would be represented in shares of the going concern. The other 2,000 shares are to be subscribed, 1,000,000fr. in cash, in the same proportion as the above contributions, and we shall have to find £16,000, and those gentlemen will have to find the balance, £24,000; and the profits realised in the future will of course follow the shares. Of every £100 profit made they get 60 per cent. and we get 40 per cent., and we think, looking at the matter all round, it is a very satisfactory bargain, and the more one looks at it the more satisfied he becomes (hear, hear). By uniting these companies on these conditions, we get rid of the litigation, and shall be able to build up a trade mark and a business of great value by the time of the expiration of the patents. We think we have done very well indeed, looking at the outlay of the two companies, in arranging for that amount of the net profit, because, after all, the number of shares represents the concrete value, which works out at 60 per cent. and 40 per cent. respectively. Under the arrangement the two companies are put together as a going concern in those countries, and there is an end of all litigation, and each party withdraws from the litigation and pays its own costs. One very important matter is this—suppose in the interval there should arise some unforeseen, as far as the present goes, necessity for terminating this bargain, which could be done in general meeting recommended by the Directors, each company would return to the *status quo ante bellum*, or perhaps I should say *ante pacem*, with all its rights intact, but not with its right to litigation. Therefore, if at the end of two or three years we should dissolve the partnership—which I cannot foreshadow, it has been provided for—it would not mean a revival of litigation. Neither party can challenge the rights of the other in the future, and that seems to be a matter of some value, looking at the cost of this litigation (hear, hear). I have told you, I think, of the chief facts. Then, there is the capital. We get 1,000,000fr. as representing what we put in in fully paid up shares, and I may say in the presence of a couple of distinguishd lawyers, one English and the other French, that the recent division does not affect the rights of any company to do what we are doing—it represents so many thousands paid down to carry on the business. These are the general terms of the agreement, but there are some exceptional things I ought to call attention to. The only charge resting on the business, over and above the cost to the parties, is that 20 centimes, and we, for reasons which are satisfactory to our minds, thought it better to accept that for the term of the patents. But there are some other conditions. We were pretty free all over Europe. We had not committed ourselves very much; and they had. They had made bargains with a very important firm, well known in this country—Sir William Siemens and Co.—who are equally powerful people in Germany and elsewhere abroad. They were large manufacturers or installers of electricity abroad, and they had made contracts with the Edison Company, under which in Austria-Hungary and Russia they are entitled to manufacture lamps as lessees upon the terms of certain royalties to the parent company. We have had to face these different arrangements, and there is no getting rid of the bargain with Siemens; but what we have stipulated is that all benefits arising under that shall come into the common pot. Siemens pays 37½ centimes for the right to manufacture the lamps, and they manufacture on a considerable scale, though not so large as to interfere with the scope of our Company. They may like to take our lamps at the trade price, or make lamps themselves and pay the royalty, and the parent company undertake to hand those royalties over. They have similar arrangements with the Italian Society and with a large firm in Belgium, and whatever the benefits are they will come into our "pot"; they are not entitled to make any charge for doing the work, and we have the power of control to the extent of examining their books. We have reserved for our Company the right to manufacture lamps in Germany, and sell them as long as the law will allow us, and if anybody chooses to buy lamps in Hamburg and any of the German ports for export, not to Great Britain, but to any parts of the world where there are no patent laws, we shall be free to do that business. There is the general character of the bargain, though, of course there are a great many details. The French Company have other business besides lamp making, such as the manufacture of dynamos, but we shall not enter into these. The fusion, of course, involves Articles of Association and the appointment of the Direction. Therefore, it becomes a matter of confidence. We are very well satisfied with the outcrop of the discussion. Of course, we go in as the minor factor, and we were careful to consider how that minor factor was to be protected from being overridden and outvoted by the major factor. What we did was to get three Directors out of a Board of seven; that still leaves the governing

Digitized by Google

power in the hands of our French friends, but we could not reasonably claim more. The Directors would be nominated for the whole term of the agreement, and it is for the shareholders to say whether they will run the risk of so nominating their Directors. The French Company have nominated Messieurs. Bernard, Chatard, Rau, and Porgés; while your interests will be represented, if you approve of this agreement, by Mr. Leyland, Mr. Simon, our agent in Paris since the formation of the Company, and who is a man of exceptional intelligence and straightforwardness, and myself. Article 12 decrees what is to be done with the net proceeds after deducting the working expenses. There is to be a reserve fund of five per cent., which is according to the common law of France; six per cent. interest on the shares; then from the balance shall be set apart ten per cent. for the Board of Directors, to be distributed amongst the members in equal parts—thus, if the shareholders do not get six per cent. the Directors will get nothing. I beg now to move

"*That the Agreement now submitted, dated the 5th May, 1888, and made between the Swan United Electric Light Company (Limited) of the one part and the Compagnie Continentale Edison de Paris of the other part be and the same is hereby approved, and that the Directors be empowered to do all acts necessary for carrying such Agreement into effect, and constituting the new company, and to enter into a further agreement to be made with such new company.*"

The Chairman explained that the further agreement referred to a bargain with the Edison and Swan Company not to make lamps for exportation to those countries protected by Swan's patents.

Mr. LEYLAND seconded the motion, and expressed an opinion that when the new arrangement was found to work well Germany would reconsider its position, and come to similar terms. He recommended entering into the agreements which had been described by the Chairman as the very best thing the Company could do (applause).

Mr. BERNSTINGL and Mr. B. T. THOMPSON put several questions in response to an invitation to do so, and they were duly answered by the Chairman.

The motion was then put, and carried unanimously.

The meeting then closed with a vote of thanks to the Chairman.

The Western Counties and South Wales Telephone Company.

The following report of the Directors of the above Company for the year ended 31st December, 1887, was presented to the shareholders at the third annual ordinary general meeting of the Company, held yesterday, the 7th instant.

Capital Expenditure.—The capital expenditure for the year ended the 31st December, 1887, has been £28,789. 15s. 11d., making a total of £85,290. 16s. 8d. to date.

Revenue.—The gross revenue of the Company for the year 1887 was £23,597. 10s. 5d., against £15,406. 11s. 1d., for the year ended 31st December, 1886.

Working Expenses. — The working expenses for the year 1887 have been £6,693. 8s. 3d., against £4,898. 17s. 10d. for the year ended 31st December, 1886.

Dividend.—Balance of net revenue account £5,397. 19s. 9d. Dividend of 6 per cent. on the paid up Preference share capital for the year ended 31st December, 1887, £4,310. 9s. 5d. For appropriation of balance, see statement at end of accounts, £1,087. 10s. 4d.

Ordinary Capital.—The Directors desire to state that although the progress of the Company has been such as would have justified them in recommending the payment of a dividend on these shares, they consider it best to defer doing so for this year. The opening of the Company's system of trunk wires has necessitated a large amount of capital expenditure (see paragraph relating to trunk wires), at present practically unproductive, and the general revenue of the year has therefore to bear the burden of the Preference dividend on the capital outlay.

Growth of Business.—It will be seen from the following figures that the growth of the business of the Company for the past year has been very rapid; the number of subscribers to the Company's exchange system having considerably increased, while there has been a satisfactory addition to the number of private line renters. The subscribers to the various exchanges and the private line renters on the 31st December, 1887, and on the 31st December, 1886 (including orders on hand), were as follows:—

	Exchange.	Private.	Total.
December 31st, 1887	1,572	462	2,034
December 31st, 1886	993	325	1,318
Increase in 1887	579	137	716

Mileage of Trunk and Renters' Wires.—Erected up to 31st December, 1887, 2,140 miles; erected up to 31st December, 1886, 1,163; increase in 1887, 977.

Trunk Wires.—The amount expended in extending trunk wires up to 31st December, 1887, has been £18,874. 3s. 8d., while the rentals applicable to that year are only £210. 1s. 10d., but the Directors look forward with confidence to the current year bringing in a substantial revenue from the trunk wire system.

Additional Capital.—To enable the Company to carry out the contemplated extensions of business it will be necessary to raise additional capital, and the Directors propose to create a further amount of £100,000 in 20,000 Preference shares of £5 each.

The following resolution was submitted for the consideration of the meeting:—

"*That the capital of the Company be increased £500,000 by the creation of twenty thousand new Preference shares of £5 each, which shares shall be entitled to receive out of the profits of the Company a cumulative preferential dividend of £6 per cent. per annum on the amount for the time being paid up on such new Preference shares respectively; and in case of any final distribution of assets, the amount paid up, or credited as paid up, on such new Preference shares shall be paid out of the assets of the Company in priority to the amount paid up, or credited as paid up, on the Ordinary shares, and the said new Preference shares shall be entitled to the same privileges, and shall be subject to the same conditions in other respects as the original Preference shares, so far as the same privileges and conditions are respectively applicable to the circumstances; and the said new Preference shares may be issued by the Directors either as and under the name of Second Preference shares, subject to the prior rights and privileges attaching to the original Preference shares, or with the consent of the holders of the original Preference shares in accordance with the provisions of Article 39, the said new Preference shares may be issued on an equality with the original Preference shares.*"

Borrowing Powers.—The following resolution was submitted for the consideration of the meeting:—That the following Article shall be substituted for Article No. 71, namely:—

"*They may borrow any sum or sums of money on such security and terms as to interest or otherwise as they may deem fit, and may secure the same by mortgage or other debentures, or by bonds or other securities, or by any mortgage or charge of or upon the whole or any part of any property, funds, assets, or effects of the Company or its uncalled capital, but so that not more than £20,000 be owing at any time without the consent of a general meeting, and provided that not more than £10,000 of the said money shall be borrowed without the consent, in writing, of the United Telephone Company (Limited), and no borrowed money shall, without the like consent, carry interest at a higher rate than 6 per cent. per annum.*"

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN

The Post Office.—The Directors are pleased to state that the relations of the Company with the Post Office officials are satisfactory.

Retiring Directors.—The following Directors, Messrs. Charles Nash and Richard Cory, retire by ballot, but, being eligible, offer themselves for re-election.

Auditors.—Messrs. Tribe, Clarke and Co. retire in accordance with the Articles of Association.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended May 25th, 1888, are estimated at £4,125, and for the week ended June 21st, at £3,376.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of May was 4,437, estimated to produce £3,300, against 4,040 messages, producing £3,061 in the corresponding month of last year. The traffic receipts for the month of February, estimated at £3,600, realised £3,666.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May, 1888, amounted to £1,800, and to £1,568 in the corresponding period of 1887.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May, 1888, amounted to £40,586, and to £36,495 in the corresponding period of 1887.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May, 1888, amounted to £49,003, and to £48,057 in the corresponding period of 1887.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company are as follows:—Receipts in May, 1888, £23,200; from January 1st to May 31st, 1888, £108,400; corresponding months, 1887 and 1886, £103,520 and £100,960 respectively.

STANDARD ELECTRIC LIGHT AND POWER COMPANY (in liquidation). A meeting of the creditors of this company will be held at the office of the company, 7, Westminster-chambers, Victoria-street, Westminster, S.W., at 11 a.m. on Wednesday, the 13th inst. "to consider the offer of a new company for the purchase of the whole of the assets of the above named company, for a sum that will enable the legal and other expenses to be paid and the creditors to receive 5s. in the £;" and "to pass such resolutions as the creditors may consider desirable."

UNITED TELEPHONE COMPANY.—The directors recommend a dividend for the second half-year ended 30th April, 1888, at the rate of 10s. per fully paid share and 5s. on the new shares, making, with the interim dividend paid on the 2nd December last, a total dividend for the twelve months of 15 per cent., as compared with 13 per cent. for the previous twelve months.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended May 25th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,366, and for the week ended June 1st, £2,675.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the month ended 31st May amounted to £4,700.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month to May 31st, 1888, are £2,991, as compared with £3,438 in 1887. February receipts, estimated at £6,449, realised £6,625.

PERSONAL.—Mr. Frank Kitchell, representing the firm of Augustus Noll and Co., of New York, the agents of the Sawyer-Man Company, is at present in England, with a view to introduce the Sawyer-Man system of electric lighting into England and France.

SUBMARINE CABLE COMPANIES.

December, 1887.

(Compiled by LEWIS WELLS, F.S.S.)

FENN and CO., LD.

10, RAILWAY APPROACH, LONDON BRIDGE, S.E.

SPECIALITIES.

WIRE-CUTTING PLIERS. DRAW VICES.
SHIPS' LANYARDS.
PORTABLE VICE BENCHES. TOOL CHESTS.

ALL KINDS OF HAND AND BENCH TOOLS FOR RAILWAY, TELEGRAPH, AND TELEPHONE MECHANICS.

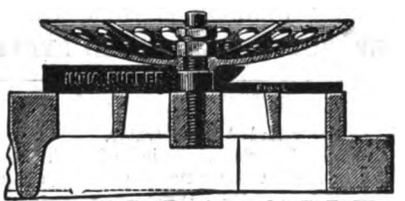
LATHES, SHAPING, DRILLING, AND PLANING MACHINES, SHAFTING, PULLEYS, BELTING, &c.

Contractors for most of the Government Departments.

ESTABLISHED IN 1665.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.
"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the uties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 526.—Vol. XXI. FRIDAY, JUNE 15, 1888. Price 4d.

NOTES.

In another column will be found a report of a most phenomenal character upon the behaviour of a secondary cell which has recently been brought out in Germany under the name of the "Tudor" Accumulator. If the report had been signed with a name of any less authority than that of Prof. Kohlrausch we should have been disposed to dismiss the statements as very much too good to be true. It is a pity that the experiments were not carried out upon a scale commensurate with practical work. A full-size battery rarely behaves quite in the same way as one or two selected cells. We also regret that the report contains so little information with regard to the construction of the plates. But after all that can be said in depreciation it seems impossible to doubt that the results obtained by Prof. Kohlrausch mark a very distinct advance in secondary batteries, such as may well gladden the hearts of the advocates of what Mr. Crompton is pleased to call the B.-T. system.

Our issue of the 25th of May contained an abstract of a Paper by Prof. Galileo Ferraris describing a method of producing a revolving resultant magnetic field by means of a pair of coils with their axes at right angles, and traversed by alternating currents, and we drew attention to the possibility that the principle of this apparatus might be applied to the construction of an alternating-current motor. The Paper by Mr. Nicola Tesla, which appears in our columns this week, contains a description of such a motor, founded on exactly the same principle.

In our correspondence columns will be found a very interesting communication from the Postmaster-General of South Australia describing the arrangements which have been carried out in order to effect telephonic connection between Port Adelaide and the mail steamers lying at anchor in the Gulf of St. Vincent. It will be seen that the arrangement is of a very simple character, and also that it is quite successful. The same thing has been done by or for the Messageries Maritimes Company at Havre, as we described in February last; and it will also be remembered that a cable of nine miles in length connects the Sunk lightship to the Post Office at Walton-on-the-Naze; but this, as a permanent connection, scarcely comes under the same category. It is, however, surprising that the convenience and utility of such a device has not long ago led to its far more frequent use. To take only one instance, at Liverpool the Transatlantic liners always lie at anchor in mid-stream for some ten or twelve hours before their final departure, and one would suppose that telephonic communication with the shore would be of very considerable service. We recommend Mr. Todd's interesting communication to the attention of all concerned with either telephonic or shipping enterprise.

At the meeting of the Académie des Sciences on the 7th of May, M. Blondlot described an experiment which he apparently believed to be new, according to which a tube filled with a weak solution of perchloride of iron, a paramagnetic salt, immersed in a stronger solution of the same salt, and placed between the poles of an electro-magnet, sets itself, like a diamagnetic body, at right angles to the lines of force. M. Blondlot takes it for granted that the tube when immersed in the stronger solution still becomes magnetised like iron, and he adduces the experiment as a proof that Tyndall's crucial experiment, showing the diamagnetic polarity of bismuth, can be explained on Becquerel's theory, namely, that the magnetic permeability of diamagnetic bodies is less than that of space, while that of paramagnetic bodies is greater. At the following meeting, M. Mascart asserted that while the experiment was in accordance with Becquerel's theory, M. Blondlot was not warranted in assuming the magnetisation of the tube to be the same as that of iron, for theory shows that when the magnetisation is proportional to the magnetising force, as is found to be the case with all diamagnetic and feebly paramagnetic bodies, the superficial magnetisation of a body changes its sign when the body is removed from a medium of less to one of greater permeability than its own, and the effect of this superficial magnetisation is all that can be observed. The experiment is by no means a new one, being given in the first edition of "Maxwell's Electricity and Magnetism," as an illustration of Faraday's theory that the phenomena were simply due to a tendency in diamagnetic bodies to move from stronger to weaker parts of the magnetic field. Maxwell shows that where the coefficient of magnetisation is so small that the induced magnetisation of the body produces only such slight alteration of the forces in the magnetic field that the magnetic force within the body may, to a first approximation, be assumed to be the same as if the body had not been there, the effect of the superficial distribution of magnetism is such as to make a paramagnetic body in a medium of greater magnetic permeability than its own behave as though it were diamagnetic.

THE unique position of the Sheffield Telephone Exchange Company has, as was to be expected, led to litigation between it and the United Telephone Company. The arrangement temporarily enjoined by Mr. JUSTICE KAY is, perhaps, in the circumstances, as fair and satisfactory to both parties as could be expected. To prevent, on the one hand, a wilful infringement of the last named company's patents, and to protect, on the other, the Sheffield Company from being extinguished by the patentees, it has been decided that good and practical telephones shall be supplied to the Sheffield Exchange in place of its worn out or obsolete patterns, pending a final settlement of the main points in dispute. The very existence of the Sheffield Exchange Company is, no doubt, threatened; but if Mr. JUSTICE KAY's remarks on Friday last may be taken as an indication of what is likely to happen, we may anticipate that some conclusion less disastrous than this will be arrived at. Whether the Sheffield Company owes its existence to fortunate accident or to commercial foresight, the fact remains that it has discharged its functions satisfactorily; and to deprive it of the means of carrying on a business honestly acquired would be, it seems to us, not only unfair but highly impolitic.

THE French Atlantic Cable Company do not appear to have profited much by their withdrawal from the pool. According to the report of the directors just issued, the working expenses of the company during the past year amounted to £67,000, the net earnings reaching only a trifle over £23,000. The actual receipts are given as £68,873; but from this sum £45,800 had to be paid out to foreign and other companies—a large portion, no doubt, being swallowed up in payments made to them during the four serious interruptions to which the company's own cable was subjected, and which would have cost nothing beyond their repairs had the company remained in the pool. It is instructive to note also the confession of the directors that the sixpenny tariff has not answered the expectations formed respecting it. In point of fact, this experiment of working an Atlantic cable independently at the sixpence-a-word rate has proved a disastrous failure.

AMONG the uncovenanted European servants of the Indian Government there are, we believe, a considerable number attached to the Telegraph Service, many, indeed, occupying positions of great responsibility. It appears from what transpired in the Parliamentary discussion on Mr. KING'S motion last Friday that some of the more crying grievances of the uncovenanted telegraph officers have been remedied, their status in respect to pay and leave of absence being now assimilated to that of the covenanted service. But they are still in the same position as regards their prospective pensions, which, owing to the fall in the value of the rupee, have within the last ten years been reduced by about 30 per cent., and may probably fall even lower. The motion for an inquiry was rejected by 166 against 55, chiefly on the ground that to pay the pensions in sterling would give rise to a claim for the salaries also to be paid in sterling. We fancy, however, the subject will not be allowed to drop on such a plea as this, seeing that the salaries are paid in India, where the relative value of the sovereign and rupee remains unaltered, the pensions alone, which are mostly paid in England, being affected by the difference of exchange.

DISCUSSION on our national defences goes on as briskly and as hotly as ever, and with as little appearance of agreement among those who take part in it. Two things, however, have been declared with precision—first, that an invasion is possible, and, secondly, that when it takes place we have only to repel it by pouring every available man upon the landing force and exterminating it. No doubt; but granting that a sudden landing is possible, it is possible at almost any point of a very long stretch of our southern coast; and this being the case, the number of "available men" at any given point must be limited by our knowledge of what point is being selected by the invaders. Only by the instrumentality of the telegraph can such information be communicated with sufficient rapidity, and at present there is certainly no continuous line of telegraph along the accessible coast to serve this useful purpose.

WE have received this week a copy of the thirteenth edition of "The Phœnix Fire Office Rules." In the present edition Mr. HEAPHY has eliminated the greater portion of the saving clauses to which so much objection was taken at the Society of Telegraph-Engineers and Electricians, in so far that they are no longer included in the rules. As, however, it would be practically impossible to draw up a set of regulations applicable to every case that may occur without leaving anything to the discretion of the inspector, a clause has been added to the effect that "No departure whatever from any of these rules will be allowed, unless express permission is given by the inspector from the fire office. The whole of the work and materials must be to his entire satisfaction." The first part of Rule 21 in the present edition, namely, "Where accumulators or primary batteries are used, the mains, both positive and negative, must have a switch and a cut-out upon each," is worded better than the corresponding clause in former editions, where the term double-pole was used in reference to the switches and cut-outs, which might possibly tend to encourage the practice of bringing the conductors near together, and placing both the switches or cut-outs on the same base, which is very undesirable.

THE use of torches for fishing purposes at night-time is necessarily restricted to the capture of fish in shallow waters, or of those which swim near the surface, and if, as seems to be the case, the use of the electric light can be made to diminish in any degree the uncertainty of the deep-sea fisherman's pursuit, it will be hailed as another of the long series of benefits which electricity has conferred upon us. If, however, incandescent lamps come to be generally used we shall expect to hear of amateur fishermen who have added a lamp and battery to their fishing gear telling dismal stories of sport brought to an abrupt and unexpected conclusion through a conger or a dogfish preferring the lamp to the bait, and carrying it off to digest at its leisure. In all seriousness such an event is by no means impossible, and if the lamps are used for line fishing they will have to be provided with some protection against piscine voracity.

SOME of our readers may remember that Dr. RICHARDSON once advocated the slaughtering of animals intended for human food by means of electricity. We do not exactly recollect the object; but the idea was splendid, and, like many another sanitary reform, it failed only because it did not succeed. The electric shock, Dr. RICHARDSON now informs us, is quite capable of killing, and generally does kill; but sometimes it fails, and the result of his experiments went to satisfy him that the deadly effect of the electric current on living bodies could not always be relied upon. He therefore agrees with the *Lancet* that the New York authorities are acting a little recklessly in adopting the electric current for the performance of capital punishment. And so think we. But really, when the learned doctor goes on to advise that the *coup de grâce* of the electric shock be always supplemented by a "*post-mortem* examination" to avoid the risk of "burying the victim *alive*," we should like to ask him—unless he is an Irishman, in which case no explanation is needed—which of two deaths would be preferable, that of burial alive or——. But the subject is too grim for jesting; and we note the palpable bull only as evidence of the doctor's extreme anxiety to prevent a public scandal, or worse.

The Electric Lighting Act Amendment Bill.—Lord Thurlow's Bill passed through Committee on Monday.

Epernay.—The Epernay Gas Company has decided to supply electricity for lighting purposes.

Domestic Lighting.—Mr. W. Abercrombie is introducing the electric light throughout the whole of his new house at Brooklands, the work being in the hands of Messrs. Drake and Gorham.

The Lighting of Queenstown.—Tenders are invited for lighting the public streets of Queenstown by electricity, and are to be lodged with Mr. Jas. Ahern, clerk to the commissioners, Town Hall, by the 2nd prox.

St. James's and the Electric Light.—The St. James's and Pall-mall Electric Light Company were on Thursday week last granted, by the unanimous voice of the vestry, a license for the supply of the electric light in the parish of St. James's.

Racing Telegrams.—During the morning and afternoon of Friday last 7,300 messages were sent from the Manchester Grand Stand, including 32,000 words for the press. This was the heaviest day's work ever known at the Manchester Meeting.

Scarlet Day at Cambridge.—Among the recipients of honorary degrees conferred at Cambridge last Saturday, an unusual proportion belonged to the scientific profession. Prof. Stokes, Prof. Cayley, Lord Rayleigh, Prof. Adams, and Sir F. Abel were thus distinguished.

Bologna University.—Among the recipients of honorary degrees at the recent celebration of the eighth centenary of the University of Bologna, we note the names of Sir William Thomson, Prof. Cayley, Prof. Huxley, and Prof. Adams, upon whom the Doctorate in Science was conferred.

Berlin.—The Schwartzkopf Company has recently constructed a new locomotive for electrical traction purposes. The current is supplied by a battery of 60 accumulators, of 320 ampere-hour capacity. The motor is of the disc pattern, with two windings on the armature and two commutators.

The Petroleum Engine.—A company has been formed, with a capital of £150,000 in shares of £5 each, to acquire and work the American patents of the Priestman petroleum engine n the United States. The purchase consideration is £100,000 in cash and shares, leaving £50,000 as working capital.

Brighton Electric Railway.—At a special meeting of the Town Council on Wednesdey, convened to consider a report from the Works Committee, recommending that the proprietor of the electric railway running from the Aquarium to Paston-place groyne should be required to remove his plant, it was decided by 21 votes to seven to retain the electric railway.

City and Guilds of London Technical Institute Old Students' Association.—At the next meeting of this association, which will be held on Wednesday, the 20th inst., at 7:30 p.m., Mr. W. J. Tomes will read a Paper on "Milling Machines." The association will hold their next smoking concert on the following Wednesday, the 27th inst., at Anderton's Hotel, Fleet-street.

Birmingham.—The scheme of the Midland Electric Lighting and Power Company for lighting the block of buildings in Birmingham bounded by Corporation-street, New-street, and Union-street, is said to be making slow progress, owing to the reluctance of many of the shopkeepers to dispense with the costly gas fittings with which many of their premises have recently been provided.

The Electric Light at Bristol Cathedral.—The electric lighting of Bristol Cathedral, which we announced in a recent issue as about to be carried out on the Thomson-Houston system by Messrs. Laing, Wharton and Down, was completed last week. Twenty-five arc lights, each of 1,200 candle-power, are fitted up in the nave, the temporary orchestra, and the choir, and incandescent lamps have been placed in the passages.

Society of Telegraph-Engineers and Electricians, Students' Meeting.—The last meeting of the students of this Society was held on the 9th inst., Prof. J. Perry, M.E., D.Sc., F.R.S., in the chair. The following Paper was read:—"Belts and Belt Driving," by J. N. Cooper. A discussion followed, in which Messrs. Marsh, Paul, Lamb, Mitchell, Sanders, M'Mahon, Poynton, Rance, Hume, Shephard, and Allan took part.

Edison-Swan v. Holland.—We understand that it has now been arranged that the experiments which are to be carried out by order of the judge will be conducted on the part of the plaintiffs by Dr. Hopkinson and Prof. Dewar, and on the part of the defendants by Profs. Crookes and S. P. Thompson. Prof. Stokes will act as moderator, and will make an independent report. The experiments were only commenced a few days ago and are expected to occupy a week or ten days.

Tangier and the Telegraph.—The laying by the Eastern Telegraph Company of a cable between Tangier and Gibraltar, thus placing Tangier in telegraphic communication with the civilised world, is, in the opinion of Consul White, the most important step in advance that has been made in that backward country for many years. The *Investors' Guardian* also says that "it has proved an inestimable boon to those engaged in commerce in that country, as, indeed, to all residents; and, if current report speaks true, is a great financial success. The Moorish Government had for many years opposed the laying of this cable, and great credit is due to Her Majesty's Minister for having at last overcome this opposition."

The Iron and Metal Trades Exhibition.—Under the above title an exhibition, certified by the Board of Trade as "International," is to be held at the Royal Agricultural Hall,

Digitized by Google

Islington, in November of the present year. Although this is a private venture, yet the success of the various trade exhibitions which have already been conducted in the same hall under the management of Mr. Etherington may be taken as a guarantee of the success of the present undertaking. Electrical manufacturers are not specifically included in the title of the exhibition, but we gather that an effort will be made to secure a representative display under this head, and we commend the scheme to the attention of our readers.

The Police Telegraph System.—Since the riots which took place in the West End, and the meetings of the unemployed in Trafalgar-square, the attention of the authorities has been directed to the perfecting and extension of the police telegraph system throughout the metropolis. The scheme has been carried out on an extensive scale. The central police offices are connected either by telegraph or telephone with the fire brigade stations, the War Office, the Home Office, the House of Commons, and the House of Lords, as well as with the private residences of the superior officers. In addition to these extensions, in case of emergency a message handed in at any postal telegraph office by a police officer is to take precedence of any others.

The Hanover-square School of Electrical Engineering and Submarine Telegraphy.—The managers of this school have just appointed Mr. Charles Capito, Member of the Institute of Mechanical Engineers and M.S.T.E. and E., to the post of senior instructor, soon to be vacant by the resignation of Mr. Henry D. Wilkinson. Mr. Capito was for three years apprenticed to mechanical engineering works in Copenhagen, and studied for seven years in the Polytechnical Academy there, passing all the examinations with the highest honours. Subsequently he held office in the City and Guilds of London Institute at Finsbury, under Prof. Ayrton, for about two years, when he became chief electrician to the Electrical Power Storage Company.

Boys Struck by Lightning.—On Saturday evening, says the *Manchester Guardian*, a number of boys were playing cricket close to the celebrated Crich "Stand," near Matlock Bath, when, a thunderstorm visiting the district, they took shelter in the basement of the structure, which has an elevation of 1,000ft. above the level of the sea. A flash of lightning struck the "stand," and seven boys were thrown to the ground and injured. Fears were entertained that a number were killed, but with the assistance of Dr. Graves, of Crich, five were restored and enabled to proceed home. The other two, Thomas Holmes and Arthur Tomlinson, were most seriously injured, and remained in an unconscious condition for four hours. As yet they are not declared out of danger.

The Telephone in the Western Counties.—The Western Counties and South Wales Telephone Company have issued an excellent map, showing the present position and contemplated extensions of their system. At this moment the latter (that is to say, the contemplated extensions) are considerably in excess of the work actually carried out, but seeing that the increase in the mileage of wires is now proceeding at a rate of something like 50 per cent. per annum, it does not seem likely that this condition of affairs will be of permanent duration. From the accounts rendered at the meeting of the shareholders which has just been held it will be seen that the financial position is excellent, and with a continuation of the active and judicious policy which has hitherto characterised the company's operations, we have no doubt that the future will be even more successful than the past.

An "Accident" in Germany.—A very singular accident happened in Hamburg some weeks ago, according to the *Journal für Gasbeleuchtung*. In an empty back room, behind a moulding, there were a number of electric light wires. A half-inch iron gas pipe was thrust through among these, and one of the wires was broken. Its ends lay on the gas pipe and melted a hole two-fifths of an inch in diameter. When the gas was next turned on the current happened to be off, but, of course, the gas escaped through the hole in the pipe. Then, as soon as the escape was discovered, the electric current was turned on in order to look for it. Every possible precaution having thus been taken in laying the train, an explosion of a highly successful character immediately followed.

The French Government and the Telephone.—In view of the amalgamation project at home, it is interesting to hear what is thought about telephone monopoly across the Channel. The concession granted to the Société Générale des Téléphones expires in September, 1889, and there seems to be a widespread feeling that it ought not to be renewed. *Le Bulletin de l'Electricité*, in the course of a long article, urges the Government to refuse to renew this concession and to take over the whole of the telephone business itself, citing in support of their view the dictum of M. Portalis, who said in 1837 that "every new mode of rapid communication of intelligence ought to be appropriated by the State at all costs;" the article concludes by calling on the State not to permit "the profits of such a fruitful monopoly to go into the pockets of greedy cosmopolitan fiananciers."

Dundee Telephone Service.—The National Telephone Company have issued in a very handy form a "Guide to the Public Telephone Call Offices in the Dundee District and in the Towns Connected with Dundee by Trunk Wires," showing the rates in force for three minutes' conversation from any call office over any trunk wire. The issue of this guide is a proof of the extent to which the National Company have developed their service in the district north of the Tay. As soon as the completion of the Forth Bridge enables the company to bring their cables over the estuary communication will be opened up between the Dundee and the Edinburgh districts. Glasgow is already within speaking distance of Dundee by a roundabout route through Stirling, Kirkcaldy, and Cupar; but the public are not at present invited to avail themselves of the service. A much shorter route will eventually be opened up on the completion of a line now in progress between Perth and Alloa.

Exports of Telegraphic Wire, &c.—Comparing the monthly returns this year with the corresponding returns of 1887 and 1886, we find that for the first time this year last month's exports of telegraphic wires and apparatus connected therewith were larger than in the corresponding month of the two previous years. The figures for May have also brought up the aggregate from January 1st to a larger item than in the first five months of 1887, though we are still below the total for the first five months of 1886. The following is a comparative statement to date:—

EXPORTS OF TELEGRAPHIC WIRES AND APPARATUS CONNECTED THEREWITH.

	1886.	1887.	1888.
Jan. 1 to March 31 ...	£124,074	... £131,879	... £88,077
April	111,847	... 27,616	... 27,012
May	49,460	... 10,447	... 67,905
Five months.....	£285,381	... £169,942	... £182,994

Proposed New Telegraph Cable in the Hebrides.—A movement for the extension of the telegraph system in the Outer Hebrides, in order to facilitate the increasing work in the telegraphic department of the Post Office, is, we understand, likely soon to be brought under the notice of the postal authorities.

Digitized by Google

To accomplish this it is proposed that Lochmaddy, in Uist, and Dunvegan, in Skye, should be connected by a cable, the distance across the Minch between those two places being rather less than 24 miles, thus making a direct communication between the southern portion of the Long Island and the mainland. The scheme, if carried out, would very materially expedite the transmission of messages, which by the existing arrangement, and more particularly in busy seasons, is very slow and complicated. This is more especially felt while the herring fishing lasts, when owing to the large amount of telegraphic business done on the line which connects Castlebay and Stornoway with the mainland, all local and intermediate business is frequently at a standstill.

Copper.—The *Investors' Guardian*, commenting on what it considers the critical position of the Copper Syndicate, says :—"If we take it that the contracts of the Syndicate with the Copper Companies have about three years to run from December last, and that the excess of receipts over deliveries continues at the same ratio, this excess will then amount to 146,208 tons. If the quantity purchased by the company in order to advance the price from £40 to £80 per ton was only 25,000 tons, the stock unsold in their hands on the 31st December, 1890, will amount to 171,208 tons. It is possible that the deliveries may somewhat increase, even if the high price should continue, but these would be more than counterbalanced by the product from new sources of supply over which the company has now no control." The plan for taking over the liabilities of the Copper Syndicate in Paris by the formation of a new company, with a capital of £7,000,000, has been ill-received in this country, and is severely handled by most of the English financial organs.

A New Constant Cell.—MM. Fabingi and Farkas in a communication to the Académie des Sciences on the 4th inst. described a new constant cell devised by them. It consists of a small platinum vessel coated on the inside with a compound having the empirical composition $Na_2 H_{12} Pt_2 O_{11}$, and which is formed by heating the platinum in contact with caustic soda. The vessel is filled with fused caustic soda maintained in a fluid condition by means of a small gas jet. The positive electrode consists of platinum, the negative one of gas carbon. On closing the circuit the E.M.F. soon assumes a steady value as the carbonate of soda produced is continuously eliminated and deposited in a crystalline form on the free surfaces of the electrodes. The E.M.F. depends on the temperature, but the temperature coefficient is so small that with an ordinary gas flame the E.M.F. may be maintained sensibly constant for several hours. Large and sudden alterations in the external resistance only cause a momentary change in the E.M.F., which almost immediately returns to its original value.

The Electrification of Aqueous Vapour.—MM. Lang and Lecher have lately laid the results of their experiments upon the transference of electricity by water vapour before the Académie des Sciences of Vienna. It is generally known that the friction of steam against solid bodies increases its electric charge, and this phenomenon has been made use of in the well-known Armstrong machine. M. Lecher has shown by thermometric experiments that an electrified liquid evaporates more quickly than one in a neutral condition. This, however, is nothing new; M. Mascart and, more recently still, Prof. Exner have shown the same thing. M. Lecher, however, attributes the increase in the amount of vapour to energetic electrical action taking place at the surface of the liquid, and which, according to him, renders all thermometric measurements exceedingly difficult. Others have attributed the phenomenon to the actual electrification of the steam itself, and that the steam is electrified M. Lecher's experiments have shown. These investigations are very important from a purely theoretical point of view, since they tend to throw light on the theory of atmospheric electricity.

The Use of Electric Light for Sea Fishing.—In a Note under this heading in our last issue we stated that some German fishermen had been making some experiments in this direction. We now learn from *Nature* that experiments of a somewhat similar character have been successfully carried out on our own shores. On the 19th of last month, as in previous years, the Liverpool Salvage Association placed a steamer at the disposal of the Liverpool Marine Biology Committee for a three days' Whitsuntide holiday cruise. The present cruise was devoted to dredging and sounding between the Mersey and the Isle of Man, and on the first night the experiment was tried of placing a 60 candle-power Edison-Swan submarine incandescent lamp in one of the tow nets, while the other was left in the dark. Experiments were made in three, and in six fathoms of water, while the vessel was stationary, the nets being simply distended by the tide. On each occasion the net furnished with the lamps contained an abundant haul, consisting chiefly of crustaceans, while the dark one contained practically nothing. Owing to the marked effect produced by the presence of the light, lamps were placed in both nets, the next night, and similar success was obtained.

A New Galvanometer.—The *Electrical World* of the 2nd inst. contains an account of a galvanometer designed by Dr. W. E. Geyer and Mr. H. Bristol, of the Stevens Institute of Technology, Hoboken, N.J. A compound bar, formed of a wide strip of some suitable metal, such as German silver, and a wire of the same material, riveted together at short intervals, is bent into the form of the greater portion of the circumference of a circle, with the wire inside. The bar is rigidly fixed at one end, and the two metals attached to binding screws; at the other extremity the metals are connected together, and the free end is connected by gearing with an indicating band moving over a dial plate. When a current passes through the instrument the temperature of the wire is increased in a greater ratio than that of the strip, owing to its smaller radiating surface, so that the bar tends to straighten out. The instrument is very similar in its appearance and the arrangement of its gearing to the well-known Bourdon steam pressure gauge. The deflections are made proportional to the strength of current by a suitable adjustment of the gearing. It is evident that the indications of the instrument will be independent of external changes of temperature, as these will affect both the bars equally.

An Electro-Chemical Radiophone.—In a communication to the Académie des Sciences, on the 4th inst., MM. Chaperon and Mercadier described a galvanic cell made by them which is sensitive to the action of light. It consists of a plate of bright silver, and a plate of silver, covered by the electrolysis of sulphide of sodium, with a thin layer of sulphide of silver, immersed in some electrolyte other than an alkaline sulphide, water containing a trace of sulphuric acid being as good as anything. The E.M.F. is very feeble and variable, and the cell polarises very rapidly, but its current undergoes instantaneous change when exposed to daylight or even to weak artificial light. The authors investigated the rapidity of the action by exposing the cell to the beam of the oxyhydrogen light made intermittent by passing through a revolving wheel pierced with holes. A telephone was included in the battery circuit, and sounds were produced so high in the scale as to correspond to more than 1,000 vibrations a second, which showed that the electro-chemical effect must be produced in less than $\frac{1}{2000}$th

Digitized by Google

of a second. No corresponding changes are observed in the resistance of the cell, so that the effect of the light must be to cause a variation in the E.M.F.

Death by Electricity.—Dr. Richardson writes on this subject (in the *Asclepiad*) as follows:—"In some researches on the application of the electric discharge for the painless extinction of the lives of animals to be used as food, the details of which I recorded in the *Medical Times and Gazette* for the year 1869, this mode of death was anything but certain in its effects. Sheep stricken apparently into instant and irrevocable death by electricity, after a few minutes showed signs of life, and if they had not been dispatched in the ordinary way by the knife would have been restored to consciousness. The same fact has been observed in attempts to kill dogs by the electric shock, and I once published an instance in which a large dog, struck into perfect unconsciousness by the stroke from a powerful battery, was submitted to a surgical operation whilst lying, to all appearances, dead, and was yet so little affected as to make an easy and sound recovery. It need not be inferred from such facts as these that the electric shock will not kill at one discharge—it most cases it will—but, exceptionally, instead of killing outright it will simply stun, and may induce the semblance of death instead of the real event. It will be only comman humanity, therefore, for the authorities of New York, when they begin to give the *coup de grâce* by the electric shock, to supplement the process by a *post-mortem* examination of the victims, so that the act may not be crowned by burying the victims alive."

Spanish Electrical Engineers and the Electric Light.—Commenting upon a report from Cadiz to the effect that the Municipality of Ubrique had decided to adopt the electric light, the *Revista Minera*, a recognised mining, metallurgical, and engineering weekly journal, published in Madrid, fails to see how the adoption of the electric light in Spain can be satisfactorily carried out under the present conditions. Our contemporary states that the number of skilled electricians in Spain is quite inadequate for the installation and management of the electric light in a satisfactory manner. What is wanted is a body of electricians capable of supplying and managing an installation profitably. Without such a skilled *personnel*, argues the Madrid journal, "money will be spent, the electric light will be discredited, and the industry will be thrown back eight or ten years." We last week referred to the difficulties that have arisen in connection with the lighting of the Comedy Theatre, Madrid, by electricity. The *Revista Minera* complains that, notwithstanding the decisions of the civic authorities and the Theatrical Board that the installation fulfilled the requirements of the Royal Decree, the system adopted is open to grave objections. The *Revista* is totally opposed to the employment of motors for generating the electricity in theatres, especially if the engine is working when the theatre is being used. The installation at the Comedy Theatre is declared to be an excellent one of its kind, but the *Revista* strongly advocates the employment of accumulators. Any increase of expense in the installation and production of the light would, it is argued, be more than compensated by the safety and convenience of the system it advocates, viz., that of accumulators of transformers.

Bradford.—At a meeting of the Bradford Town Council on Tuesday a communication which had been received from the Local Government Board with regard to the electric lighting scheme for Bradford was read by the Town Clerk. The communication was to the effect that the authorities had had under consideration the Council's application for borrowing powers for the purposes of the scheme, and now sent down an authorisation for the Council to borrow £20,000. Alderman F. Priestman (chairman of the Gas Supply Committee) moved the adoption of the minutes of that committee, which included resolutions accepting the tender of Messrs. J. and W. Beanland for excavating, brickwork, ironfounder and smith's work, masonry, carpentering, joinery, plumbing, glazing, &c., in connection with the electric-lighting works, for £3,690; the tender of Messrs. Holdsworth and Sons for the supply and fixing of three mild steel boilers and fittings for £2,125; and the tender of Messrs. Siemens Brothers and Co. (Limited) for the supply and fixing of dynamos and all the appliances for £12,543, the total cost of the proposed installation being £18,358. Further, the committee recommended that the Council should authorise the Gas Supply Committee to apply to the Local Government Board for authority to increase the sum to be borrowed for electricity works to an amount not exceeding in the whole £25,000. Alderman Priestman said he did not think it necessary to go at any great length into the details of the proposed scheme, inasmuch as it was practically the same scheme as that which had been brought before the Council in December last, when they had passed a resolution authorising the Gas Supply Committee to spend not more than £15,000 upon the scheme. That resolution was confirmed on February 14th, when the Council instructed the Town Clerk to apply to the Local Government Board for leave to borrow £20,000 to carry out the scheme. After some discussion the resolution embodying these proposals was carried with only two dissentient votes.

The Watkin Range-Finder. — The Government have awarded the sum of £25,000 and a retaining fee of £1,000 a year for ten years to Major H. Watkin, R.A., the inventor of the position-finder which for fifteen years past has been associated with his name. Besides being an exceptionably able gunner, Major Watkin is a first-class electrician, and to this fact is mainly due the perfecting of his remarkable invention. As originally designed, an accurate chart of the anchorage or approaches to be defended was divided into squares of twelve inches to a mile, each square having recorded on it its distance from the fort, together with the elevation and deflection due to such range. The chart was then placed under the arms of an instrument at the "directing station," a retired spot, the outlook from which would not be likely to be obscured by smoke. Well-hidden "observing stations," giving half a mile of base, were also established on each side of the fort, and a man at each station followed with a telescope the movements of the object to be fired at. The telescopes being electrically connected, moved two corresponding arms on the face of the chart at the "directing station" in such a manner that the point of intersection of the arms showed the exact position of the target on the squares. On the number of any square being telegraphed from the "directing station" to the battery, it was reproduced on a dial placed between every two guns; and all that the gun detachments had to do was to train and elevate their pieces accordingly. The essential features of the subsequent and perfected apparatus are kept secret; but it may be stated that the squares are done away with, and the simple act of laying the telescope from the directing station indicates to the batteries, which in some cases may be miles away, the training and elevation; so that the guns may be laid without the target being visible from the battery. They might, for example, be fired over a hill. Nay, more, the instrument foretells the position which a moving target, such as a ship, will occupy several seconds ahead, and sends the indication to the gun commanders, who make ready. The officer at the directing station then watches through his glass, and, when the vessel arrives at the predicted position, he presses a key and fires.

UNIPOLAR INDUCTION.—II.

BY G. W. DE TUNZELMANN, B.SC.

(Continued from page 141.)

In the year 1839 W. Weber ("Resultate des Magnetischen Vereins," 1839, p. 63; *Poggendorff's Annalen*, Vol. LII., p. 352) gave an account of some experiments made by him of a character similar to some of those which we have described. The arrangement used by him consisted of a cylindrical magnet, supported by means of two steel points pressing into depressions in its ends, just as the magnet in Fig. 4 of our last article was supported vertically, and capable of being set in rapid rotation by means of a train of wheel work. At or near the centre of the magnet a copper disc was fitted over it, and this dipped into a mercury trough placed below it. Currents were then obtained through a galvanometer with its terminals in connection with the copper disc through the mercury trough and one of the steel points respectively. In a paper by Plücker, in *Poggendorff's Annalen*, Vol. LXXXVII., p. 352, 1852, an apparatus designed by Fessel, and shown in Fig. 9, is described.* It consists of a cylindrical magnet, *n s*, rigidly attached to a pulley, *a*, with a coaxial copper cylinder, *c*, rigidly attached to a pulley, *b*. The magnet is supported on the two screws *d* and *i*, which make electrical contact with its ends, and it can be prevented from rotating by tightening the screw *d*. Contact springs pressing against the cylinder are attached to the binding-screws *f*, *g*, *h*.

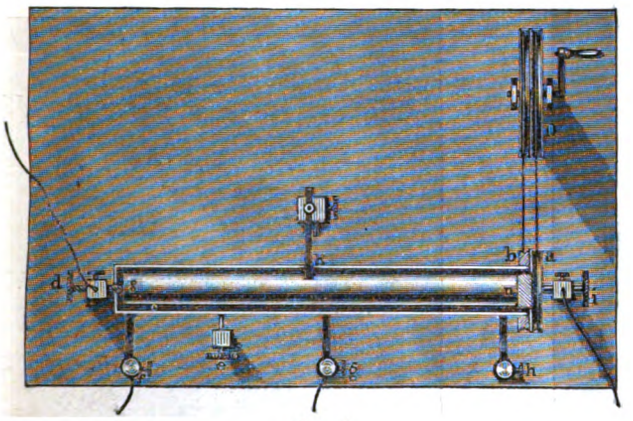

FIG. 9.

N S, steel magnet; *c*, copper cylinder; *a*, *b* and *o*, driving pulleys; *d i*, screws on which magnet turns; *f*, *g*, *h*, binding screws attached to contact springs pressing against *c*; *k*, contact spring pressing against magnet; *e*, screw for fixing cylinder.

A contact spring, *k*, passes through an opening in the cylinder, and presses against the magnet. The cylinder can be prevented from rotating by means of the screw *e*. It will therefore be seen that by means of the driving pulley O the magnet and cylinder can be rotated together, or either separately, so that the copper cylinder plays the same part as the wire *g e* in Fig. 8 of our last article, or the fixed portion of the circuit when this was removed.

If the galvanometer terminals are connected with *g* and *h*, and the magnet is rotated while the cylinder remains fixed, no current is obtained.

If the magnet and cylinder rotate together, or if the magnet is fixed and the cylinder rotates, a current in the same direction and of the same strength is obtained in each case.

If the cylinder is fixed and the galvanometer terminals connected, one with *k* and the other with *d* or *i*, a current is obtained, the arrangement being similar to that of Fig. 4 in our last article.

If the magnet and cylinder are placed in electrical contact and rotated together, and the galvanometer terminals are connected, one with *g* and the other with *d* or *i*, the current obtained is stronger than in the preceding experiment.

Fig. 10 shows a piece of apparatus in which a magnet, *n s*, and two copper discs, *a* and *b*, can be made to rotate about a common axis, and contact springs *c* and *d* press against the two discs. If the terminals of a galvanometer are connected with the binding screws to which *c* and *d* are attached, a current will always be produced on rotating the magnet, when, as shown in the figure, the contact point *d* is farther from the axis than *c*. If *d* is close to the axis and *c* at some distance from it a current will be produced in the opposite direction on rotating the magnet in the same direction as before. It will be found that no current will be obtained for a given position of *c*, when *d* is at a point slightly nearer to the axis, the difference between the

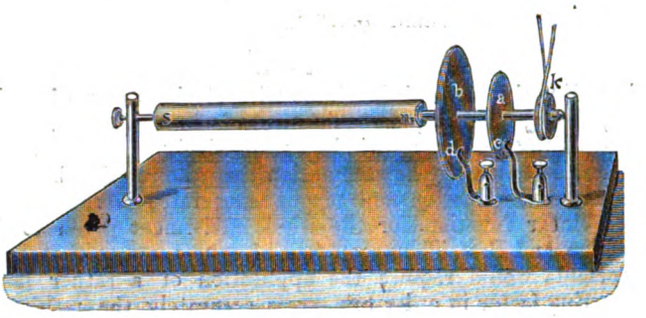

FIG. 10.

N S, steel magnet; *k*, driving pulley; *a* and *b*, copper discs; *c* and *d*, contact springs.

distances of *c* and *d* from the axis, for no current, being increased by moving *b* nearer to the magnet or *a* farther from it.

If the two springs are arranged to make contact with the same disc, but at different distances from the centre, as shown in Fig. 11, a current will also be obtained.

If the electrodes *c* and *d* are fixed to the magnet and rotate with it, while the disc *a* remains fixed, a current will be obtained in the same direction as if *c* and *d* were fixed, while the disc rotated with the magnet.

Finally, if the magnet and the electrodes are both fixed, and the disc is made to rotate in the opposite direction to that of its former rotation with the magnet, a current will be obtained in the same direction as before.

We may here note that in all cases where a current is produced by rotation of the magnet, or of a conductor in its magnetic field, if the galvanometer be replaced by a battery giving a current in the same direction as that through the galvanometer

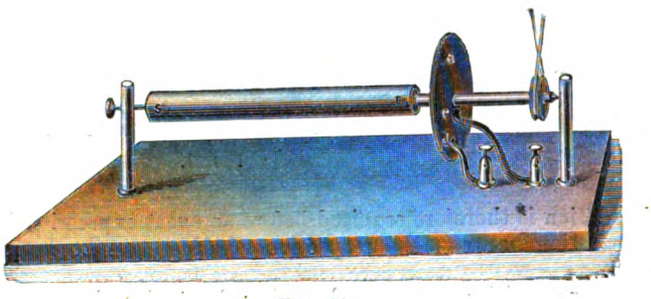

FIG. 11.

N S, steel magnet; *a*, copper disc; *c* and *d*, contact springs.

a rotation will be produced in the opposite direction to that which produced the current, as, of course, follows from Lenz's law.

(To be continued.)

* This and the two following illustrations are taken from Wiedemann's "Lehre von der Electricität."

A Collodion Electroscope.—Prof. Jouravski, of St. Petersburg, has discovered that the dry pellicle of collodion becomes negatively electrified when stretched. It is only necessary to pour a little collodion on a plate of glass and allow the ether to evaporate, when an extremely thin membrane remains behind, which is easily detached from the glass. All that has now to be done is to cut the membrane into strips and keep them in a dark place, and you have so many ready-made electroscopes.

NOTE ON THE CONDITIONS OF REGULATION IN DYNAMOS FOR CONSTANT POTENTIAL.

BY W. B. ESSON.

In *The Electrician* of May 18th is given the abstract of a short Paper on the above subject recently read by Prof. Silvanus P. Thompson before the Physical Society. It will be remembered that in his book on "Dynamo-Electric Machinery," Prof. Thompson gives for the proportion between the shunt and series windings on a constant potential machine the relation

$$\frac{Z}{S} = \frac{r_s}{r_a + r_m},$$

where Z is the turns of the shunt wire, S the turns of series wire, and r_s r_a and r_m the resistances of shunt-winding, armature-winding and series-winding respectively. The above expression is based on the assumption that the relation between the magnetic induction and magnetising force is represented by a linear function for the whole excitement given to the machine, and Prof. Thompson was, of course, aware that such a formula would require the application of a rather large correcting factor in order to express accurately the results of practice. A correcting factor Prof. Thompson applies in the Paper referred to, but the correction is inadequate, and further elucidation is therefore required before an exact expression for the relation between the respective windings can be formulated.

In two articles contributed to *The Electrician* three years ago the writer stated in a general way the principal reason why the above formula could not express the relation in actual machines. It was said that owing to the partial saturation of the magnets by the shunt coil, the value per ampere-turn of the series winding was much less than the value per ampere-turn of the shunt. The former was also shown to be proportional to the tangent of the angle which the saturation curve of the machine made with the horizontal at the point representing the excitement given to the magnets when there was no current flowing in the external circuit. Were there no correction necessary save that required by the saturation effect, Prof. Thompson's amended formula would undoubtedly be right, but inasmuch as there are other considerations which cannot be neglected, any formula which recognises the circumstance referred to as alone influencing the regulation will not give accurate results.

The curve (Fig. 1) reproduced by the courtesy of Messrs. Paterson and Cooper, and obtained from one of their "Phœnix" dynamos, will illustrate the remarks which follow. The machine was of the single-magnet upright-type similar in design to the one illustrated in *The Electrician*, Vol. XX., page 568, and compound-wound for 150 100 volt 16 candle-power lamps. The ring core of the armature had about 22 square inches of iron in its cross-section, and was wound with 180 convolutions. The magnet had a cross-section of 62 square inches. At 1,420 revolutions per minute the machine had an output of 90 amperes at 100 volts. The curve was obtained by running the machine at this speed, and exciting the magnets from the shunt-coil only, introducing resistances to vary the excitement There was no current in the armature save that going round the shunt, and no lead was given to the brushes. The exciting current and E.M.F. being simultaneously observed, the curve in which the former in ampere-turns is plotted as abscissæ and the latter as ordinates gives the "satural" data of the machine.

If in a compound dynamo with long-shunt winding v is the difference of potentials required at the terminals, V the difference of potentials required to send the external current through the armature and series coil, i_1 the current in the shunt and i_2 the external current, then $\frac{v}{i_1(Z+S)}$ and $\frac{V}{i_2 S}$ as measured from the curve Fig. 1 represent the ratios which were called the mean value per ampere-turn of the shunt and series windings respectively. They are the ratios of induced magnetism to magnetising force, and are now termed by Prof. Thompson the average permeability corresponding to no external current, and the average permeability over the working range. These can be determined quite easily from the curve. Calling the former p_1 and the latter p_2, since to produce a given effect the product of the turns and permeability is a constant, we have, inserting these factors,

$$\frac{Z}{S} \times \frac{p_1}{p_2} = \frac{r_s}{r_a + r_m}$$

as the amended expression for the relation between the shunt and series windings; in other words, the correcting factor is the ratio of the average permeability over the range of excitement on open circuit to the average permeability over the excitement range of the series wire.

The formula thus modified would doubtless express the relation which Prof. Thompson wishes it to express were there no current flowing in the armature, no reactions therefrom, no self-induction, and no magnetic leakage. As it stands dynamo makers well know that the series turns which it indicates are still too few. The correction is, in fact, based upon

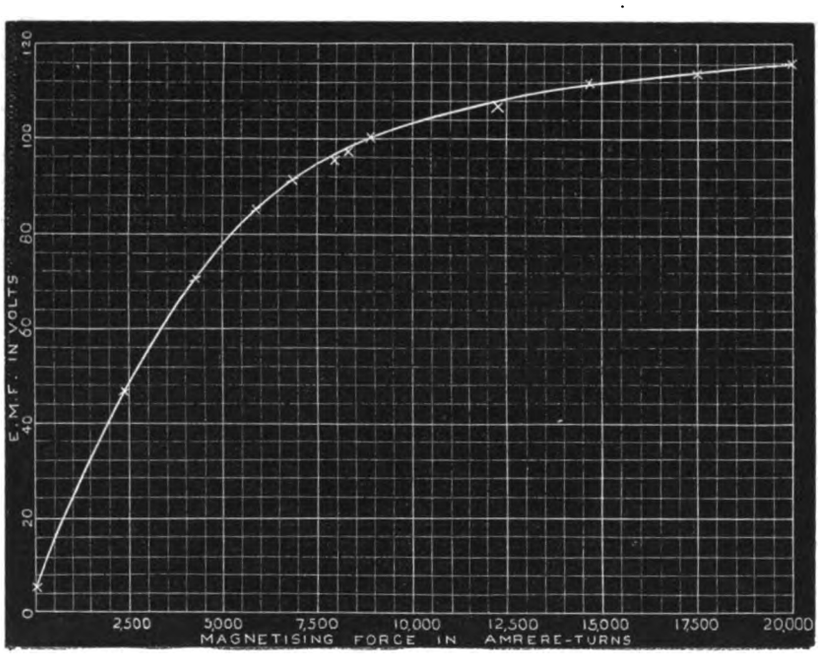

FIG. 1.

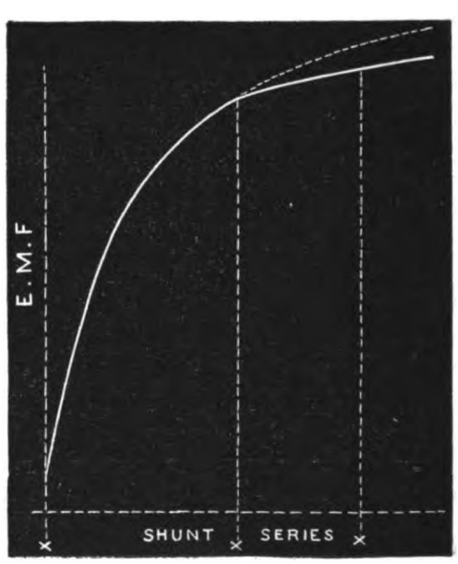

FIG. 2.

Digitized by Google

another assumption, which is not justified by practice, and that is that the curve connecting the E.M.F. with the magnetising force is, after the series wire comes into action and a current flows in, a continuation of the curve due to the excitement on open circuit. That this is not the case, that there is an angle in the curve, as in Fig. 2, is shown by a very simple experiment. Run the machine on open circuit to obtain the necessary E.M.F., say 100 volts, and measure the excitement given to the magnets. Now run with the circuit closed, the brushes having their proper lead, and the full current flowing through the armature, the machine giving the same virtual E.M.F. as before. The difference of potential at the brushes will now be 100 volts, *minus* the difference of potentials required to send the current through the armature. It will be found that the excitement required to obtain this has been considerably increased, and the difference represents what might be called the waste excitement. These turns cannot be utilised to add to the E.M.F.; their function is purely compensatory, if one might say so, counteracting the fall of potential due to the influences above mentioned. If, the conditions remaining otherwise similar, the excitement is further increased until the E.M.F. required to send the current through the armature and series is added, the increase represents the turns inductively serviceable. The turns thus added probably accord with those which would be indicated by the saturation curve of the machine.

On examining the curve of the dynamo referred to, it will be seen that 8,750 ampere-turns were required to produce an E.M.F. of 100 volts. The resistance of the armature and series coil was ·061 ohm, and the E.M.F. required to send through this resistance the external current of 90 amperes was, roughly, 5·5 volts. The resistance of the shunt was 650 times that of the armature and series. From the curve we learn that 105·5 volts can be produced by a magnetising force of 11,000 ampere-turns, or, 8,750 being furnished by the shunt and series on open circuit, 2,250 ought to be added by the series when 90 amperes are flowing. This is the series excitement as indicated by the "satural" data, but, as a matter of fact, in this machine there were added 4,860 ampere-turns, the total excitement on full load being 13,610. The above is a very usual proportion for the windings of compound machines.

It appears, then, that a further modification in the formula is necessary, and that it is delusive to deduce the amount of series wire from the satural data alone, since there are several considerations besides this which determine the relation of the shunt and series windings. In the writer's opinion these considerations are too important to be neglected in any formula by which it is desired to express with exactitude this relation. It would seem desirable, moreover, to abandon a formula by which it is attempted to express it in terms of the resistances of the coils and armature, the utility of such a formula not being apparent to those engaged in dynamo construction.

A NEW ALTERNATING CURRENT MOTOR.

BY NICOLA TESLA.*

In the presence of the existing diversity of opinion regarding the relative merits of the alternate and continuous current systems, great importance is attached to the question whether alternate currents can be successfully utilised in the operation of motors. The transformers, with their numerous advantages, have afforded us a relatively perfect system of distribution, and although, as in all branches of the art, many improvements are desirable, comparatively little remains to be done in this direction. The transmission of power, on the contrary, has been almost entirely confined to the use of continuous currents, and notwithstanding that many efforts have been made to utilise alternate currents for this purpose, they have, up to the present, at least as far as known, failed to give the result desired. Of the various motors adapted to be used on alternate current circuits the following have been mentioned: (1) A series motor with subdivided field. (2) An alternate-current generator having its field excited by continuous currents. (3) Elihu Thomson's motor. (4) A combined alternate and continuous current motor. Two more motors of this kind have suggested themselves to me: (1) A motor with one of its circuits in series with a transformer, and the other in the secondary of the transformer. (2) A motor having its armature circuit connected to the generator, and the field coils closed upon themselves. These, however, I mention only incidentally.

The subject which I now have the pleasure of bringing to your notice is a novel system of electric distribution and transmission of power by means of alternate currents, affording peculiar advantages, particularly in the way of motors, which I am confident will at once establish the superior adaptability of these currents to the transmission of power, and will show that many results heretofore unattainable can be reached by their use, results which are very much desired in the practical operation of such systems, and which cannot be accomplished by means of continuous currents.

Before going into a detailed description of this system I think it necessary to make a few remarks with reference to certain conditions existing in continuous current generators and motors, which, although generally known, are frequently disregarded.

In our dynamo machines, it is well known, we generate alternate currents which we direct by means of a commutator—a complicated device, and, it may be justly said, the source of most of the troubles experienced in the operation of the machines. Now, the currents so directed cannot be utilised in the motor, but they must—again by means of a similar unreliable device—be reconverted into their original state of alternate currents. The function of the commutator is entirely external, and in no way does it affect the internal working of the machines. In reality, therefore, all machines are alternate-current machines, the current appearing as continuous only in the external circuit during their transit from generator to motor. In view simply of this fact, alternate currents would commend themselves as a more direct application of electrical energy, and the employment of continuous currents would only be justified if we had dynamos which would primarily generate, and motors which would be directly actuated by such currents.

But the operation of the commutator on a motor is twofold—firstly, it reverses the currents through the motor; and, secondly, it effects, automatically, a progressive shifting of the poles of one of its magnetic constituents. Assuming, therefore, that both of the useless operations in the system—that is to say, the directing of the alternate currents on the generator, and reversing the direct currents on the motor—be eliminated, it would still be necessary, in order to cause a rotation of the motor, to produce a progressive shifting of the poles of one of its elements, and the question presented itself, how to perform this operation by the direct action of alternate currents. I will now proceed to show how this result was accomplished.

In the first experiment a drum armature was provided with two coils at right angles to each other, and the ends of these coils were connected to two pairs of insulated contact rings, as usual. A ring was then made of thin insulated plates of sheet iron and wound with four coils, each two opposite coils being connected together so as to produce free poles on diametrically opposite sides of the ring. The remaining free ends of the coils were then connected to the contact rings of the generator armature so as to form two independent circuits, as indicated in Fig 9. It may now be seen what results were secured in this combination, and with this view I would refer to the diagrams Figs. 1 to 8A. The field of the generator being independently excited, the rotation of the armature sets up currents in the coils varying in strength and direction in the well-known manner. In the position shown in Fig. 1 the current in coil c is *nil* while c_1 is traversed by its maximum current, and the connections may be such that the ring is magnetised by the coils c_1 c_1, as indicated by the letters N S in Fig. 1A, the magnetising effect of the coils c c being *nil*, since these coils are included in the circuit of coil c.

In Fig. 2 the armature coils are shown in a more advanced position, one-eighth of one revolution being completed. Fig. 2A illustrates the corresponding magnetic condition of the ring. At this moment the coil c_1 generates a current of the same direction as previously, but weaker, producing the poles n_1 s_1 upon the ring; the coil c also generates a current of the same direction, and the connections may be such that the coils c c produce the poles n s, as shown in Fig. 2A. The resulting polarity is indicated by the letters N S, and it will be observed that the poles of the ring have been shifted one-eighth of the periphery.

In Fig. 3 the armature has completed one-quarter of one revolution. In this phase the current in coil c is a maximum, and of such direction as to produce the poles N S in Fig. 3A, whereas the current in coil c_1 is *nil*, this coil being at its neutral position. The poles N S in Fig. 3A are thus shifted one-quarter of the circumference of the ring.

Fig. 4 shows the coils in a still more advanced position, the armature having completed three-eighths of one revolution. At that moment the coil c still generates a current of the same direction as before, but of less strength, producing the comparatively weaker poles n s in Fig. 4A. The current in the coil c_1 is of the same strength, but of opposite direction. Its effect is therefore to pro-

* Paper read before the American Institute of Electrical Engineers, May 15th, 1888.

Digitized by Google

duce upon the ring the poles n_1 and s_1 as indicated, and a polarity N S results, the poles now being shifted three-eighths of the periphery of the ring.

In Fig. 5 one-half of one revolution of the armature is completed, and the resulting magnetic condition of the ring is indicated in Fig. 5A. Now, the current in coil c is *nil*, while the coil c_1 yields its maximum current, which is of the same direction as previously; the magnetising effect is therefore due to the coils c_1 c_1 alone, and referring to Fig. 5A it will be observed that the poles N S are shifted one-half of the circumference of the ring. During the next half revolution the operations are repeated, as represented in the Figs. 6 to 8A.

A reference to the diagrams will make it clear that during one revolution of the armature the poles of the ring are shifted once around its periphery, and each revolution producing like effects a rapid whirling of the poles in harmony with the rotation of the armature is the result. If the connections of either one of the circuits in the ring are reversed, the shifting of the poles is made to progress in the opposite direction; but the operation is identically the same. Instead of using four wires, with like result, three wires may be used, one forming a common return for both circuits.

The rotation or whirling of the poles manifests itself in a series of curious phenomena. If a delicately-pivoted disc of steel or

other magnetic metal is approached to the ring it is set in rapid rotation, the direction of rotation varying with the position of the disc. For instance, noting the direction outside of the ring, it will be found that inside the ring it turns in an opposite direction, while it is unaffected if placed in a position symmetrical to the ring. This is easily explained. Each time that a pole approaches it induces an opposite pole in the nearest point on the disc, and an attraction is produced upon that point; owing to this, as the pole is shifted further away from the disc, a tangential pull is exerted upon the same, and the action being constantly repeated, a more or less rapid rotation of the disc is the result. As the pull is exerted mainly upon that part which is nearest to the ring, the rotation outside and inside, or right and left, respectively, is in opposite directions. When placed symmetrically to the ring, the pull on opposite sides of the disc being equal, no rotation results. The action is based on the magnetic inertia of the iron; for this reason a disc of hard steel is much more affected than a disc of soft iron, the latter being capable of very rapid variations of magnetism. Such a disc has proved to be a very useful instrument in all these investigations, as it has enabled me to detect any irregularity in the action. A curious effect is also produced upon iron filings. By placing some upon a paper, and holding them externally quite close to the ring, they are set in a vibrating motion, remaining in the same place, although the paper may be moved back and forth; but in lifting the paper to a certain height, which seems to be dependent on the intensity of the poles and the speed of rotation, they are thrown away in a direction always opposite to the supposed movement of the poles. If a paper with filings is put flat upon the ring, and the current turned on suddenly, the existence of a magnetic whirl may be easily observed.

To demonstrate the complete analogy between the ring and a revolving magnet, a strongly energised electromagnet was rotated by mechanical power, and phenomena identical in every particular to those mentioned above were observed.

Obviously, the rotation of the poles produces corresponding inductive effects, and may be utilised to generate currents in a closed conductor placed within the influence of the poles. For this purpose it is convenient to wind a ring with two sets of superimposed coils, forming respectively the primary and secondary circuits. In order to secure the most economical results, the magnetic circuit should be completely closed, as shown in Fig. 10, and with this object in view the construction may be modified at will.

The inductive effect exerted upon the secondary coils will be mainly due to the shifting or movement of the magnetic action; but there may also be currents set up in the circuits in consequence of the variations in the intensity of the poles. However, by properly designing the generator, and determining the magnetising effect of the primary coils, the latter element may be made to disappear. The intensity of the poles being maintained constant, the action of the apparatus will be perfect, and the same result will be secured as though the shifting were effected by means of a commutator with an infinite number of bars. In such case the theoretical relation between the energising effect of each set of primary coils and their resultant magnetising effect may be expressed by the equation of a circle having its centre coinciding with that of an orthogonal system of axes, and in which the radius represents the resultant and the coordinates both of its components. These are then respectively the sine and cosine of the angle a between the radius and one of the axes (OX). Referring to Fig. 11 we have $r^2=x^2+y^2$; where $x=r\cos a$, and $y=r\sin a$.

Assuming the magnetising effect of each set of coils in the transformer to be proportional to the current—which may be admitted for weak degrees of magnetisation—then $x=\mathrm{K}c$ and $y=\mathrm{K}c_1$, where K is a constant and c and c_1 the current in both sets of coils respectively. Supposing further, the field of the generator to be uniform, we have for constant speed $c_1=\mathrm{K}^1\sin a$ and $c=\mathrm{K}^1\sin(90^\circ+a)=\mathrm{K}^1\cos a$, where K^1 is a constant (*see* Fig. 12). Therefore

$$x=\mathrm{K}c=\mathrm{K}\,\mathrm{K}^1\cos a;$$
$$y=\mathrm{K}c_1=\mathrm{K}\,\mathrm{K}^1\sin a, \text{ and}$$
$$\mathrm{K}\,\mathrm{K}^1=r.$$

That is, for a uniform field the disposition of the two coils at right angles will secure the theoretical result, and the intensity of the shifting poles will be constant. But from $r^2=x^2+y^2$ it follows that for $y=0$, $r=x$; it follows that the joint magnetising effect of both sets of coils should be equal to the effect of one set when at its maximum action. In transformers and in a certain class of motors the fluctuation of the poles is not of great importance, but in another class of these motors it is desirable to obtain the theoretical result.

In applying this principle to the construction of motors, two typical forms of motor have been developed. First, a form having a comparatively small rotary effort at the start, but maintaining a perfectly uniform speed at all loads, which motor has been termed synchronous. Second, a form possessing a great rotary effort at the start, the speed being dependent on the load.

These motors may be operated in three different ways:—(1) By the alternate currents of the source only; (2) by a combined action of these and of induced currents; (3) by the joint action of alternate and continuous currents.

The simplest form of a synchronous motor is obtained by winding a laminated ring provided with pole projections with four coils, and connecting the same in the manner before indicated. An iron disc having a segment cut away on each side may be used as an armature. Such a motor is shown in Fig. 9. The disc being arranged to rotate freely within the ring, in close proximity to the projections, it is evident that as the poles are shifted it will, owing to its tendency to place itself in such a position as to embrace the greatest number of the lines of force, closely follow the movement of the poles, and its motion will be synchronous with that of the armature of the generator; that is, in the peculiar disposition shown in Fig. 9, in which the armature produces by one revolution two current impulses in each of the circuits. It is evident that if, by one revolution of the armature, a greater number of impulses is produced, the speed of the motor will be correspondingly increased. Considering that the attraction exerted upon the disc is greatest when the same is in close proximity to the poles, it follows that such a motor will maintain exactly the same speed at all loads within the limits of its capacity.

To facilitate the starting, the disc may be provided with a coil closed upon itself. The advantage secured by such a coil is evident. On the start the currents set up in the coil strongly energise the disc, and increase the attraction exerted upon the same by the ring, and currents are generated in the coil as long as the speed of the armature is inferior to that of the poles. Considerable work may be performed by such a motor, even if the speed be below normal. The intensity of the poles being constant, no currents will be generated in the coil when the motor is turning at its normal speed.

Instead of closing the coil upon itself, ends may be connected by two insulated sliding rings, and a continuous current supplied to these from a suitable generator. The proper way to start such a motor is to close the coil upon itself until the normal speed is reached, or nearly so, and then turn on the continuous current. If the disc be very strongly energised by a continuous current the motor may not be able to start; but if it be weakly energised, or generally so that the magnetising effect of the ring is preponderating, it will start and reach the normal speed. Such a motor will maintain absolutely the same speed at all loads. It has also been found that if the motive power of the generator is not excessive, by checking the motor the speed of the generator is diminished in synchronism with that of the motor. It is characteristic of this form of motor that it cannot be reversed by reversing the continuous current through the coil.

The synchronism of these motors may be demonstrated experimentally in a variety of ways. For this purpose it is best to employ a motor consisting of a stationary field-magnet, and an armature arranged to rotate within the same, as indicated in Fig. 13. In this case the shifting of the poles of the armature produces a rotation of the latter in the opposite direction. It results therefrom that when the normal speed is reached, the poles of the armature assume fixed positions relatively to the field-magnet, and the same is magnetised by induction, exhibiting a distinct pole on each of the pole-pieces. If a piece of soft iron is approached to the field-magnet, it will at the start be attracted with a rapid vibrating motion produced by the reversals of polarity of the magnet; but as the speed of the armature increases the vibrations become less and less frequent, and finally entirely cease. Then the iron is weakly but permanently attracted, showing that the synchronism is reached, and the field-magnet energised by induction.

The disc may also be used for the experiment. If held quite close to the armature it will turn as long as the speed of rotation of the poles exceeds that of the armature; but when the normal speed is reached, or very nearly so, it ceases to rotate, and is permanently attracted.

A crude but illustrative experiment is made with an incandescent lamp. Placing the lamp in circuit with the continuous-current generator, and in series with the magnet coil, rapid fluctuations are observed in the light, in consequence of the induced currents set up in the coil at the start; the speed increasing, the fluctuations occur at longer intervals, until they entirely disappear, showing that the motor has attained its normal speed.

A telephone receiver affords a most sensitive instrument; when connected to any circuit in the motor the synchronism may be easily detected on the disappearance of the induced currents.

In motors of the synchronous type it is desirable to maintain the quantity of the shifting magnetism constant, especially if the magnets are not properly subdivided.

To obtain a rotary effort in these motors was the subject of long thought. In order to secure this result it was necessary to make such a disposition that while the poles of one element of the motor

Digitized by Google

are shifted by the alternate currents of the source, the poles produced upon the other element should always be maintained in the proper relation to the former, irrespective of the speed of the motor. Such a condition exists in a continuous-current motor; but in a synchronous motor, such as described, this condition is fulfilled only when the speed is normal.

The object has been attained by placing within the ring a properly subdivided cylindrical iron core wound with several independent coils closed upon themselves. Two coils at right angles are sufficient; but a greater number may be advantageously employed, as in Fig. 14. It results from this disposition that when the poles of the ring are shifted currents are generated in the closed armature coils. These currents are the most intense at or near the points of the greatest density of the lines of force, and their effect is to produce poles upon the armature at right angles to those of the ring, at least theoretically so; and since this action is entirely independent of the speed—that is, so far as the location of the poles is concerned—a continuous pull is exerted upon the periphery of the armature. In many respects these motors are similar to the continuous current motors. If load is put on, the speed, and also the resistance of the motor, is diminished, and more current is made to pass through the energising coils, thus increasing the effect. Upon the load being taken off, the counter E.M.F. increases, and less current passes through the primary or energising coils. Without any load the speed is very nearly equal to that of the shifting poles of the field-magnet.

It will be found that the rotary effort in these motors fully equals that of the continuous-current motors. The effort seems to be greatest when both armature and field-magnet are without any projections; but as in such dispositions the field cannot be very concentrated, probably the best results will be obtained by leaving pole projections on one of the elements only. Generally, it may be stated that the projections diminish the torque, and produce a tendency to synchronism.

A characteristic feature of motors of this kind is their capacity of being very rapidly reversed. This follows from the peculiar action of the motor. Suppose the armature to be rotating, and the direction of rotation of the poles to be reversed. The apparatus then represents a dynamo machine, the power to drive this machine being the momentum stored up in the armature, and its speed being the sum of the speeds of the armature and the poles. If we now consider that the power to drive such a dynamo would be very nearly proportional to the third power of the speed, for this reason alone the armature should be quickly reversed. But simultaneously with the reversal another element is brought into action, viz., as the movement of the poles with respect to the armature is reversed, the motor acts like a transformer in which the resistance of the secondary circuit would be abnormally diminished by producing in this circuit an additional E.M.F. Owing to these causes the reversal is instantaneous.

If it is desirable to secure a constant speed, and at the same time a certain effort at the start, this result may be easily attained in a variety of ways. For instance, two armatures, one for torque and the other for synchronism, may be fastened on the same shaft, and any desired preponderance may be given to either one, or an armature may be wound for rotary effort; but a more or less pronounced tendency to synchronism may be given to it by properly constructing the iron core, and in many other ways.

As a means of obtaining the required phase of the currents in both the circuits, the disposition of the two coils at right angles is the simplest, securing the most uniform action; but the phase may be obtained in many other ways, varying with the machine employed. Any of the dynamos at present in use may be easily adapted for this purpose by making connections to proper points of the generating coils. In closed-circuit armatures, such as used in the continuous-current systems, it is best to make four derivations from equi-distant points or bars of the commutator, and to connect the same to four insulated sliding rings on the shaft. In this case each of the motor circuits is connected to two diametrically opposite bars of the commutator. In such a disposition the motor may also be operated at half the potential and on the three-wire plan, by connecting the motor circuits in the proper order to three of the contact rings.

In multipolar dynamo machines, such as use the converter systems, the phase is conveniently obtained by winding upon the armature two series of coils, in such a manner that while the coils of one set or series are at their maximum production of current the coils of the other will be at their neutral position, or nearly so, whereby both sets of coils may be subjected simultaneously or successively to the inducing action of the field-magnets.

Generally, the circuits in the motor will be similarly disposed, and various arrangements may be made to fulfil the requirements; but the simplest and most practicable is to arrange primary circuits on stationary parts of the motor, thereby obviating, at least in certain forms, the employment of sliding contacts. In such a case the magnet coils are connected alternately in both the circuits; that is, 1, 3, 5 in one, and 2, 4, 6 in the other, and the coils of each set of series may be connected, all in the same manner, or alternately in opposition; in the latter case, a motor with half the number of poles will result, and its action will be correspondingly modified.

The employment of multipolar motors secures in this system an advantage much desired and unattainable in the continuous current system, and that is, that a motor may be made to run exactly at a pre-determined speed, irrespective of imperfections in construction of the load, and within certain limits, of E.M.F. and current strength.

In a general distribution system of this kind the following plan should be adopted:—At the central station a supply generator should be provided having a considerable number of poles. The motors operated from this generator should be of the synchronous type, but possessing sufficient rotary effort to insure their starting. With the observance of proper rules of construction, it may be admitted that the speed of each motor will be in some inverse proportion to its size, and the number of poles should be chosen accordingly. Still exceptional demands may modify this rule. In view of this, it will be advantageous to provide each motor with a greater number of pole projections or coils, the number being preferably a multiple of two and three. By this means, by simply changing the connections of the coils, the motor may be adapted to any probable demands.

If the number of the poles in the motor is even the action will be harmonious, and the proper result will be obtained; if this is not the case the best plan to be followed is to make a motor with a double number of poles, and connect the same in the manner before indicated, so that half the number of poles result. Suppose, for instance, that the generator has twelve poles, and it would be desired to obtain a speed equal to 12/7 of the speed of the generator. This would require a motor with seven pole projections or magnets, and such a motor could not be properly connected in the circuits unless fourteen armature coils were provided, which would necessitate the employment of sliding contacts. To avoid this, the motor should be provided with fourteen magnets, and seven connected in each circuit, the magnets in each circuit alternating among themselves. The armature should have fourteen closed coils. The action of the motor will not be quite so perfect as in the case of an even number of poles, but the drawback will not be of a serious nature.

However, the disadvantages resulting from this unsymmetrical form will be reduced in the same proportion as the number of the poles is augmented.

If the generator has, say, n, and the motor n_1 poles, the speed of the motor will be equal to that of the generator multiplied by $\frac{n}{n_1}$.

The speed of the motor will generally be dependent on the number of the poles, but there may be exceptions to this rule. The speed may be modified by the phase of the currents in the circuits or by the character of the current impulses, or by intervals between each or between groups of impulses. Some of the possible cases are indicated in the diagrams Figs. 18, 19, 20, and 21, which are self-explanatory. Fig. 18 represents the condition generally existing, and which secures the best result. In such a case, if the typical form of motor illustrated in Fig. 14 is employed, one complete wave in each circuit will produce one revolution of the motor. In Fig. 19 the same result will be effected by one wave in each circuit; in Fig. 20 by two, and in Fig. 21 by four waves.

By such means any desired speed may be attained; that is, at least, within the limits of practical demands. This system possesses this advantage besides others, resulting from simplicity. At full loads the motors show an efficiency fully equal to that of the continuous-current motors. The transformers present an additional advantage in their capability of operating motors. They are capable of similar modifications in construction, and will facilitate the introduction of motors, and their adaptation to practical demands. Their efficiency should be higher than that of the present transformers, and I base my assertion on the following:—

In a transformer as constructed at present we produce the currents in the secondary circuit by varying the strength of the primary or exciting currents. If we admit proportionality with respect to the iron core, the inductive effect exerted upon the secondary coil will be proportional to the numerical sum of the variations in the strength of the exciting current per unit of time; whence it follows that for a given variation any prolongation of the primary current will result in a proportional loss. In order to obtain rapid variations in the strength of the current, essential to efficient induction, a great number of undulations are required and employed. From this various disadvantages result. These are increased cost and diminished efficiency of the generator, more waste of energy in heating the cores and also diminished output of the transformer, since the core is not properly utilised, the reversals being too rapid. The inductive effect is also very small in certain phases, as will be apparent from a graphic representation, and there

Digitized by Google

may be periods of inaction, if there are intervals between the succeeding current impulses or waves. In producing a shifting of the poles in the transformer, and thereby inducing currents, the induction is of the ideal character, being always maintained at its maximum action. It is also reasonable to assume that by a shifting of the poles less energy will be wasted than by reversals.

PROF. G. FORBES ON TRANSFORMERS IN THE STATES.

The current issue of the *Journal* of the Society of Telegraph-Engineers and Electricians (No. 73, Vol. XVII.) contains the report of the discussion on Mr. Crompton's Paper "On Continuous Current *versus* Alternating Current Transformers." To the report of Prof. Forbes's speech (see *Electrician*, May 4th, p. 749, Vol. XX.) the following "postscript" is added :—

Having been asked by the Society to add some further account of the manner of working converters in America, I will now briefly comply with that request.

Engines and Dynamos.—It is a mistake to suppose that one or two large engines are more economical than a number of small ones. A large engine working far below its power is very wasteful of steam.

One engine drives one dynamo by belt direct, without countershafting. It is well to have each unit in a station of the same size, so that parts are interchangeable and the attendant has less to think of. The size of the unit may be chosen so as to supply, at sufficient load, the minimum current required in the twenty-four hours. One exciter is generally used for four machines in series, with an adjustable resistance. A shunt resistance largely made up of lamps may be put on each field for regulation.

Feeders.—These are generally overhead. Waring cable underground (lead-covered) is perfectly successful. Simplex wire is generally used for overhead work. Five or six feeders are often fed by one dynamo. A loss of 2 to 2½ per cent. of potential is generally adopted. Double bell insulators are used.

Converters.—These are made for 5, 10, 20, 30, and 40 lights. The wiring of a large house is best done with separate circuits for each 40 lights. It is unadvisable to "bank" or group in parallel a number of converters. These converters are very light, and have a smaller quantity of iron than might be thought good. They reduce the potential from 1,000 to 50 volts. The primary and secondary fuses are put inside the converter. The mode of manufacture of these has been described elsewhere. The insulation between the primary and secondary coils is indestructible.

Lamps.—It is found that 50-volt lamps last longer than those with thinner filaments, and are generally used. The potential in the primary is 1,000 volts. No man has ever been killed by a 1,000-volt alternating current. It is well here to mention that you cannot get an arc from the low-potential circuit when an alternating current is used.

Meters.—The Westinghouse Company has made such arrangements as will enable them to charge customers by means of the coulomb-meter.

Station Ampere-Meters.—The same instrument as Edison uses is adopted, but with a bundle of wires sucked into the coil. Both the bundle and the coil form part of an arc of a circle, and the former moves on an axis at the centre of the circle. The force of the current acts against the weight of a counterpoise, and an index indicates the amperes.

Station Voltmeter.—A "three-point" converter reduces the potential either ten-fold or twenty-fold. A compound-wound "compensator" reduces the measured potential to that at the centre of consumption. The voltmeter is solenoidal in action, and is true only when the speed of engine is quite constant. The wire bundles for these solenoids are ingeniously constructed. A metal cylinder is covered with varnished paper or muslin. Iron wire is wound round the cylinder, sticking to the varnish. The iron wire ring thus formed is cut through and a flat web of iron wire is produced, which can be cut into lengths and rolled into bundles.

Ground Detector.—Two converters have a lamp on each secondary. The primaries are connected in series to the mains. The intermediate contact is connected to earth. If one of the mains has an earth its lamp goes out. A multiple switch is provided by which each circuit can be tested in turn.

Synchroniser.—To synchronise any two dynamos, secondary wires are led to a switch-board. A wire from one converter is connected to a wire from the other. The two other wires are connected through two lamps. If the connected wires are in the same phase the lamps go out. A switch is provided by which, as soon as the lamp goes out, the second dynamo is connected to the mains of the first. The dynamos work well in parallel from half to full load. Allegheny station sometimes calls to Pittsburg, across the river, for assistance in current, and the synchronism is good. Synchronism is found to be quite satisfactory from half to full load, but not below.

Switch-Boards.—A switch-board is generally set up for each dynamo, and for five or six feeders. The conductors going to feeders run up and down; those going to dynamos are horizontal. The dynamo wires are connected with three instruments in a vertical row—an ampere meter, a converter, and a voltmeter. Each feeder has a vertical row of instruments, a three-point converter, a compensator, and a voltmeter. There are six switches for six feeders in a horizontal row, to switch any feeder into either of two pairs of dynamo conductors. One of these pairs is connected to the switch-board dynamo; the other can be connected, by means of a switch at the side of the board, to the conductors of either of the neighbouring dynamos. An adjustable resistance, with six lamps in series for additional resistance, is at the bottom and middle of the board, and acts as a shunt on the field-magnets. Another adjustable resistance is in series with all the field-magnets. Another switch connects either of two exciters with the field-magnets.

There are some other devices connected with street-lighting and theatre-lighting which I am not at liberty to describe, owing to the English patents being not yet completed.

BOOKS, &c., RECEIVED.

"Technology Quarterly." Massachusetts Institute of Technology, Vol. I., No. 4 (Boston).

"*Proceedings* of the Royal Society," Vol. XLIV., No. 267. (London: Harrison and Sons.)

MEETINGS OF SCIENTIFIC SOCIETIES.

SATURDAY, June 16th.

ROYAL INSTITUTION.

3 p.m. Lecture, "Count Tolstoi as Novelist and Thinker" (3). By Prof. C. E. TURNER, of the University of St. Petersburg.

WEDNESDAY, June 20th.

SOCIETY OF ARTS.

Annual *Conversazione.*

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting at the Institution of Civil Engineers, 25, Great George-street, Westminster. The following papers will be read :—"First Report of the Thunderstorm Committee—On the Photographs of Lightning Flashes." Drawn up by the Hon. RALPH ABERCROMBY, F.R.Met.Soc. "The Cold Period from September, 1887, to May, 1888." By Mr. CHARLES HARDING, F.R.Met.Soc, and "Observations on Cloud Movements near the Equator, and on the General Character of the Weather in the Doldrums." By the Hon. RALPH ABERCROMBY, F.R.Met.Soc.

THURSDAY, June 21st.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting.

ROYAL SOCIETY.

4:30 p.m. Ordinary Meeting.

SATURDAY, June 23rd.

PHYSICAL SOCIETY.

3 p.m. Note on "Continuous Current Transformers." By Prof. S. P. THOMPSON, D.Sc.

Ship Lighting.—The Queen's yacht "Victoria and Albert" is being lit throughout by means of the electric light, and a battery of Messrs. Drake and Gorham's largest size ship lighting cells are being installed for the supply of all the lamps which will be required at night, and also to guard against any sudden extinction of the lamps. In connection with these cells Messrs. Drake and Gorham are supplying a special switch-board fitted with their patent ring contact switches.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to The Proprietors.

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
" Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

"The Electrician" in America.

"The Electrician" can be obtained in America from D. Van Nostrand, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

The Proprietors of "The Electrician" beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued The Electricians' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

VOLUME XX. OF "THE ELECTRICIAN"

NOW READY. Bound in cloth, price Ten Shillings and Sixpence.
Also Cases for Binding, price Two Shillings.

Applications should be made to "The Publisher."

TECHNICAL EDUCATION FOR SOUTH LONDON.

Next to that of national defence, there is, perhaps, no question which at the present moment occupies so much of the attention of statesmen and philanthropists as the technical education of the working classes. Originally taken up by the City and Guilds of London, the movement has spread with a rapidity which, like the one for guarding the country against invasion, may be ascribed in some degree to panic. Industrial and commercial depression have come upon us gradually; but that they were largely due to national inferiority in technical knowledge and skill was a quite sudden discovery, and no sooner was it made than steps were taken to remedy the defects. Technical schools and colleges on an extensive and expensive scale were established and liberally endowed, and almost before they have had time to make a fair start Parliament is invoked to aid a similar system which shall cover the whole country through the agency of the Board Schools. Simultaneously private charity has come to the help of particular districts, providing them with the means of instruction which but a few years ago would have been thought superfluous and fanciful. The East End of London has been exceptionally favoured in this respect, its rivals in the South and South-West complaining that it was getting more than its rightful share of the good things going. To the fact that South London is as poor as the East, and its population, if possible, more exclusively industrial, we owe the meeting at the Mansion House last Friday, where a scheme was set on foot for establishing on the Surrey side of the Thames three Polytechnic Institutes which will vie with any that the "pampered East" can boast of. The project was influentially supported, and although a very large sum of money—£150,000—is asked for, we have no doubt that, supplemented by a similar sum promised from the Charity Commissioners, the needful endowments will be forthcoming. In the South-West of London a like appeal is being made under the promising auspices of Lord Cadogan.

Digitized by Google

The warmth with which these schemes have been backed up in the daily press is an encouraging augury for their success, although we cannot always agree with the grounds on which it has lent its powerful assistance. Lord SALISBURY, as he always does, brought some fresh ideas to bear on the subject at the Mansion House meeting. It is true that towards the end of his speech he let fall a sentence or two of those stereotyped arguments which the newspapers are never tired of repeating, such, for example, as that in the unskilled labour of the masses we cannot find the means by which the teeming millions of this country shall be able to maintain themselves in a prosperous, decent, and comfortable condition; and that our difficulties are enhanced by the fact that our neighbours in other countries have been sensible of the superiority which skilled education can confer, and have taken advantage of it to our discomfiture. But in the main the PRIME MINISTER occupied himself with more original and less questionable propositions than these. Starting with the axiom that the knowledge which we do not use and improve disappears from our memories very rapidly, he deduced the rational conclusion that the elementary education which the law has been enforcing for eighteen years past will be lost on the rising generation of workpeople unless we provide them with the means of following it up. The classes immediately above them, and those who are still higher in the social scale, are all well provided with suitable places for advancing their secondary education; but the lower classes are very ill-provided in this respect, and, quite apart from any question of industrial supremacy, it is highly expedient that this deficiency should be supplied. Indirectly, of course, the national well-being will be promoted by opening to every class, the lowest as well as the highest, the opportunities of an education which may develop for each man the faculties that nature has given him in order that he may become as intelligent, as active, and as prosperous a member of the community as possible. But a higher object than this will be achieved by assuaging that sullen discontent which so often finds vent in outbursts of political passion because the opportunities of intellectual improvement have been withheld. A still greater advantage may be looked for in raising the dignity of work by systematically insisting on its excellence; and this is a task which the technical school is best calculated to accomplish.

The proposed establishment of work-schools attached to our Board Schools has a most promising future, looked at from this point of view. The fears of those who apprehended that universal education would result in universal rebellion against manual labour have proved not wholly without foundation. As people with education before the era of Board Schools were commonly supposed to be exempted from manual labour, it has come to be thought that everybody who has obtained the education which a Board School can give has a right to this exemption; and when we remember the enormous sacrifices that have been made on mere schooling since 1870, and the little that has been done for handicraft, it need not surprise us that the latter has fallen somewhat in popular estimation while the former has risen inordinately. It is idle to deny what every honest observer knows to be the fact, and the sooner we let the scholars understand that their education is intended to improve their work, not to supersede it, the better it will be for them and for the nation. In other words, although we are more alive than formerly to the fact that the first necessity of mankind is to live, we are not absolved from inculcating that the first duty of mankind is to work; and, as Lord Salisbury puts it, the chief object of all education should be to fit them for labour which will enable them to live. These truths were not sufficiently considered when we established the scheme of primary national education under which the present generation of workmen have been reared, and it is to correct this oversight that the present movement on behalf of secondary education has been started.

One of the most satisfactory features of the programme is its voluntary character. It will be supported by public subscription, and consequently free from the obligations which a State-aided system would necessarily impose. This is of the greatest importance, for it leaves the student free to choose the particular study which suits him best. The plan which is said to have answered so well at the old Polytechnic Institute is to be followed in the new Institutes; each branch of learning is open to those who are attracted by it, but is forced upon nobody. Accepting the experience of the Polytechnic as a criterion of what may be expected from an extension of its operations, we find that secondary education may be given at a very small cost, and that it is so much in demand that any institutions we can provide will be filled as rapidly as they are built. If these expectations are realised, then it is probable, as *The Times* remarks, that the practical problem of finding the means of diffusing technical education may be solved before we have quite agreed as to why it should be promoted. Every speaker and writer seems to have his own pet reason for it; but as all are of one mind on the main point, their objects need not be criticised too closely. Sir LYON PLAYFAIR'S is perhaps as good as any other. According to him "the best educated nation, technically and industrially, will become the greatest nation, if not to-day certainly to-morrow." Evidently the ideal of national greatness here implied is not exactly that conceived by Lord SALISBURY; but this does not hinder their respective exponents working together harmoniously in a cause which both confess to be of great national importance; and indeed the secondary education and technical training of the masses are in themselves so wholesome and so invigorating, that no modern nation can afford to neglect the elements of greatness which these advantages are likely to create in the bulk of its population.

REVIEW.

Electricity and Magnetism. By E. MASCART and J. JOUBERT. Vol. II. Translated by E. Atkinson, Ph.D. (London: De La Rue and Co.).

This volume completes the translation of this well-known and, needless to say, valuable work. The first volume treated of the phenomena and the mathematical theory of electricity; this volume is devoted to electrical measurements and applications of the theory. The plan of dividing up the subject is unusual, but is natural, and very much more convenient than the usual method of mingling two branches of a subject together when they are really distinct.

The body of the work is really a treatise on exact electrical measurement for laboratory use. Much of it presupposes considerable mathematical knowledge on the reader's part, and in all cases where magnitudes of possible errors can be treated by mathematical methods they are so treated down to the minutest detail. On looking into a medical book one always feels that one has at least six fatal diseases. Similarly, after perusal of this volume, one feels that really nothing can be measured, which is, after all, the truth. Enormous care is necessary in many classes of measurement to secure an approximately accurate result.

The only weakness, if, indeed, the authors have any, is a tendency to eliminate errors by complicated calculations of their values, when in many cases they could be determined empirically with greater ease.

The authors begin by calling attention to the displacement error in weighing, which is frequently overlooked. They do not mention errors due to differences of temperature producing air currents and affecting the balance. Perhaps such an error is too elementary, but it might have been mentioned.

Digitized by Google

Considerable attention is devoted to the management and use of mirror instruments. The use of the mirror in such instruments is generally ascribed to Gauss and Weber, or to Sir W. Thomson, but the authors point out that it is due to Poggendorff. The information about suspensions is full and interesting, but we miss a definite notice of one source of error. If an instrument be made with, say, a glass, or wire suspension, it does not come to zero after torsion for some time. A glass suspension will often take a day or so to come back to the original zero after use.

Under the head of "properties of circular currents," we have the usual calculations as to the best resistance for a galvanometer. The discussion of the case in which the wire has always the same thickness of insulation might be of some use; but calculations of that in which the wire is supposed to be bare, or to have an insulation thickness proportional to the diameter, are simply reprehensible waste of paper. Of course such calculations are to be found in most books; but that is so much the worse. The authors might have copied in the table from Lord Rayleigh's "Electro-Chemical Equivalent of Silver," as useful to those who can understand it in calculating mutual induction or attraction of coils. The method of testing for leaks from one winding to another by means of an induction balance is also too important to be omitted.

The subject of self and mutual induction is fully treated, and this will be interesting to many readers. There has lately been a sort of self-induction epidemic in electrical circles. It is difficult to see what caused it, but the subject seems to have a curious fascination, though improvements in methods can be of little practical importance, as no one would want to measure coefficients of induction. We note, by the way, the omission of Ayrton and Perry's spherical needles for ballistic galvanometers.

The information as to standardising or calibrating by electrolyses of silver and copper is far too meagre. The directions would not enable anyone to get results to be relied upon.

In the discussion of the Wheatstone bridge we have the question of maximum sensitiveness, and here again, as in other books, it is assumed that the greatest sensitiveness of a galvanometer is when its internal resistance is equal to the external. We do not draw attention to this again with the wish to cavil at such a very small matter, but as another instance of the tendency of mathematical men to indulge in long and often useless calculations whenever there is the least excuse. One would imagine that an experimenter kept shelves full of galvanometers of various windings, and that when he wished to take an accurate resistance he calculated it out and selected a suitable coil or instrument, preferably wound either with bare wire or proportional insulation. Our electrical literature is full of comparatively useless calculations of this sort. The right place for most of the calculations extant about Wheatstone bridges is among the examples in a book on the differential calculus or on determinants. They might in some cases even become instructive examples.

We have the same complaint to make about the description of standard cells as about standardising by electrolysis. The information is far too meagre. It is just as important that a standard cell should be correct as that a standard resistance should. 1·435 legal volts, quoted as given by Lord Rayleigh, is inaccurate; Lord Rayleigh gave 1·435 Rayleigh volts.

Probably neither Ewing's nor Hopkinson's Papers were published in time, but we hope their experiments on iron, especially Ewing's, will find a place in the next edition.

The smaller part of the book, that on "Industrial Applications," is, in comparison with the rest, very weak; it is very inadequate, and frequently the information, such as that on accumulators, is quite out of date.

The sections on dynamos are full of false conclusions. The old fallacy of spurious armature resistance crops up, and the lead of brushes is supposed to depend on the speed; in fact we are afraid these sections are useless. The usual fallacious arguments as to output and dimensions of machines appear. It is really impossible to make such comparisons, as a large dynamo is not like a small one enlarged to scale.

In the treatment of alternate currents the authors, as might be expected, make the unwarrantable assumption that they follow the sine law, and that the circuits to be dealt with have constant coefficients of self-induction.

In conclusion, the book, written by two of the ablest experimentalists and teachers, will of course become the standard text-book of exact electrical measurement. In reviewing it, we have pointed out what we consider small blemishes, with the view that some may be corrected in future editions. To criticise such a work as this in any other sense would be absurd, as it is beyond criticism.

The translation has been very ably done by Dr. Atkinson. It generally reads as if originally writen in English. There are a few slips here and there, but they are generally unimportant. For instance, a Clark's cell is made up with mercurous sulphate, not mercuric. There are 746 watts in an English horse-power, though 736 is correct for the French horse-power. Arc tan θ is not necessarily intelligible to one who does not read French or German, and we do not call dynamos "electromotors." We only hope Dr. Atkinson has the same command of German as he has of French, and that he will soon undertake the colossal task of translating Wiedemann. German books are not only valuable in themselves, but their foot notes always give most complete references; so that, as Maxwell remarked, if you want to find what has been done on any subject, you buy a German book, which will give you references to every paper published.

The type and get up are better than in the French original; in fact, nothing is more unpleasing than a French book, which arrives dogeared, with no back, and separates into two wherever you open it. The woodcuts, however, are not so well printed in the English translation.

REPORT BY PROF. KOHLRAUSCH ON THE "TUDOR" ACCUMULATOR.

We have received from Messrs. Büsche and Müller, of Hagen, Westphalia, a copy of Prof. Kohlrausch's report on the "Tudor" accumulator, based upon experiments carried out by the professor upon a couple of cells of 45 ampere-hours' capacity. The following is an abstract of the more important points:—

Total weight of plates	29·3lb.
Surface of the four + plates	1·29 square feet.
Volume of acid	6 pints.
Specific gravity when charged	1·147
Normal charging current	5 amperes.
Normal discharging current	6·5 ,,
Internal resistance charged	·015
,, ,, discharged	·02
Capacity per pound	1·6 ampere-hours.

The two cells had already been in continuous use from 1st November, 1881, till December 22nd, 1887. During the tests they were charged and discharged thirty-four times, and between charge and discharge a period of about 15 hours was allowed to elapse. A series of six ordinary charges and discharges agreeing very well amongst themselves showed a total capacity of 47 ampere-hours, and an efficiency of 94 per cent. for current and 82·4 per cent. for work, with a drop of 12·6 per cent. for E.M.F. After this several tests of an abnormal character were made. The cells were charged, and then left alone for various periods of time; the results at first obtained generally showed a loss of 7 ampere-hours, but after this there was practically no further loss in a week. When charged with a current of 8 amperes, and discharged with 10 amperes, an efficiency of 77 per cent. and 64·7 per cent. for amperes and watts respectively was obtained. When discharged through a constant resistance, with a current beginning with 50 amperes, they gave 23·5 ampere-hours and 40·5 watt-hours, the current having fallen off at the end of the test to 40 amperes, and E.M.F. from 1·8 to 1·3 volt. They were then recharged, and discharged with 90 amperes, giving 20·1 ampere-hours and 32·7 watt-hours, the current falling to 62 amperes. After this enormous strain the cells, when recharged, gave their normal discharge just as before.

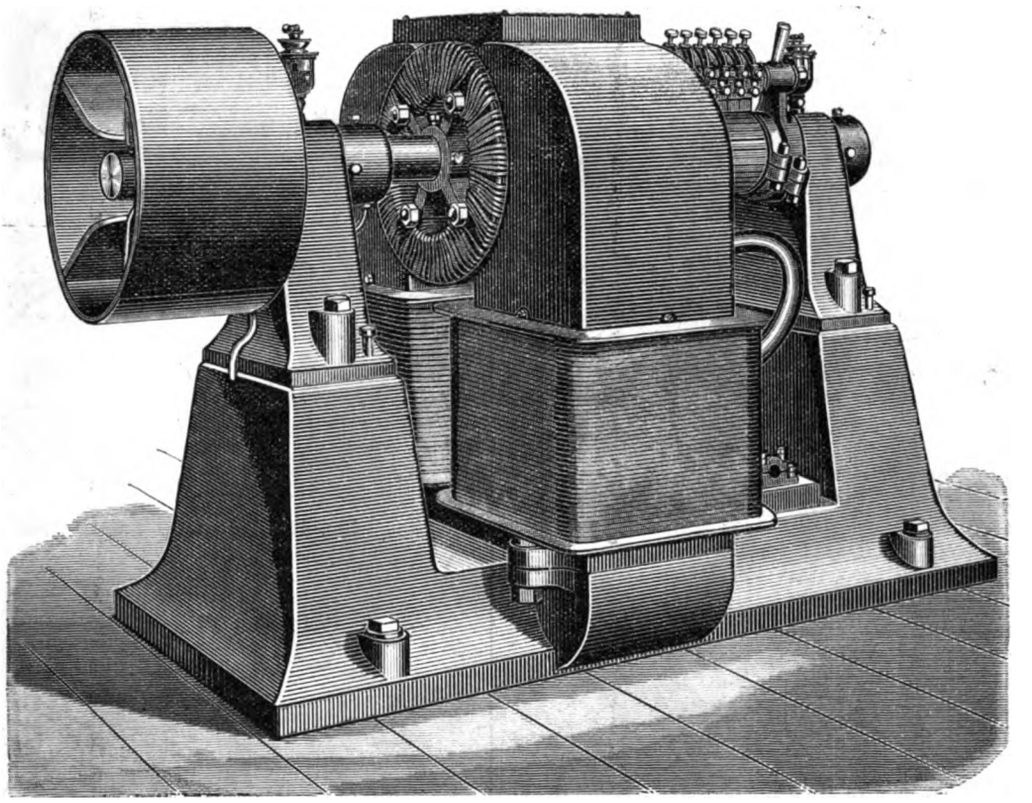
Lastly, they were run down for four days starting at one ampere until the E.M.F. had fallen to 0·2 volt and the specific

Digitized by Google

gravity of the acid to 1·1. The cells were then recharged until gas began to come off pretty freely, and on discharge they returned 46·8 ampere-hours and an efficiency of 90 per cent. for current and 80 per cent. for work.

50-UNIT DYNAMO, BY PATERSON AND COOPER.

Our illustration shows a 50-unit "Phœnix" shunt-wound dynamo, one of several recently constructed by Messrs. Paterson and Cooper for the Hermite electric bleaching process. At 600 revolutions per minute it is designed for a current of 1,200 amperes, the difference of potentials at the terminals being 42 volts. The design is very similar to that illustrated in *The Electrician*, Vol. XX., p. 568. The cross-section of the field-magnet contains 258 square inches of cast iron, and the armature core about 105 square inches of charcoal iron. The armature is wound in 38 convolutions, joined up to a 38 part collector. The resistance of the magnet coil is ·976 ohm. There are six brushes on each brush-holder, which is capable of independent spring adjustment in a direction parallel to itself. The machine measures 7ft. 3in. over the pulley in the direction of the shaft, has a width of 4ft. 4in., and a height of 4ft. 6in. The pulley is 24in. diameter, and driven by a 12in. belt.



Paterson and Cooper's 50-unit Dynamo.

"INFLUENCE MACHINES, FROM 1788 TO 1888."*

BY PROF. S. P. THOMPSON.

(Continued from page 153.)

Varley's apparatus of 1860 was followed not very many years afterwards by a whole host of beautiful devices. Holtz and Toepler in Germany produced almost simultaneously new forms of influence machines. I believe it is to Holtz that we owe the very name "Influence Machine." Sir William Thomson's machines followed a year or two later. Now to come to the devices of Toepler and Holtz. Toepler produced a very remarkable apparatus in which there were two discs going round on one shaft in the same direction. There is a drawing of it here in Figs. 8 and 9. Those two discs were excited from one side of the surface only. Take the upper plate. The disc goes round, but underneath it there is an inducing plate on one side—a field-plate. This notion of working at one side of a diameter only had, indeed, been used by Nicholson in his spinning condenser. There is a diagrammatic representation of Toepler's apparatus in Fig. 9, where one field-plate—say, for example, charged negatively—is in the neighbourhood of the rotating plate, which has two carriers on it, this being touched by a brush of some sort as they go round the second plate. The second disc is represented on this diagram as having also one field-plate, and that a positive one. Toepler made this up in several forms, some of which were highly complex. At the very same time Holtz had attacked the problem, but had solved it in quite a different way. Up to this time there had always been metallic carriers going round. Holtz abandoned the metallic carriers and depended only upon electrification which can be produced upon the surface of an insulating body such as glass. There are, of course, more ways than one of electrifying a piece of glass—one is to rub it; but there is another way, namely, to let off from points opposite to it an electrified wind. The electrified air repelled from a sharp point when it is directed to flow against the surface of the glass will charge it. That is virtually what Holtz did on that well-known machine (Fig. 10), where you have one rotating glass plate to serve as an armature and one fixed glass sheet, which has paper pieces attached to it right and left to serve as field-plates. Those paper plates are provided with tongues, which project through holes or windows cut in the fixed sheet, and serve to let off electrified winds against the back of the rotating plate, and there are two combs at the end of a rod, which let off electrified winds against the front of the plate as it goes round. Very soon after Holtz had brought out this machine it was further improved by Prof. Poggendorf, who suggested that its action might be increased by doubling the parts, by putting two fixed plates together in the middle, and then two rotating plates, one in front and one behind. A still more compact pattern of double Holtz machine was designed by Ruhmkorff. This machine is kindly lent me by Prof. Rücker for to-night, and comes from his laboratory at South Kensington. There are two interior plates which have holes through the glass windows, through which there project the paper tongues from the field-plates, as I have called them. As the glass plates go round they receive their charges in front from the action of these combs. As in Varley's machine, and as in Belli's machine, there is a conducting circuit going across the machine, the object of which is to touch the carriers whilst they are under the influence of the field-plates. Belli furnished the ends of this neutralising conductor with springs,

* A Paper read before the Society of Telegraph-Engineers on May 31st, 1888.

Digitized by Google

Varley with knobs, Holtz with spiked combs. Neither Belli nor Varley proposed to make any use of the discharge that flowed through the neutralising conductor. Varley, indeed, provided the field-plates with metal balls projecting above to give discharges.

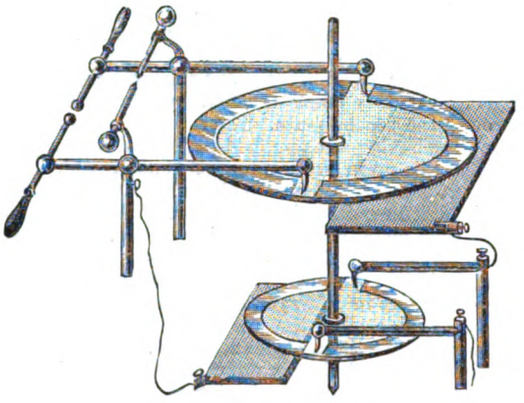


FIG. 8.—Toepler (1865).

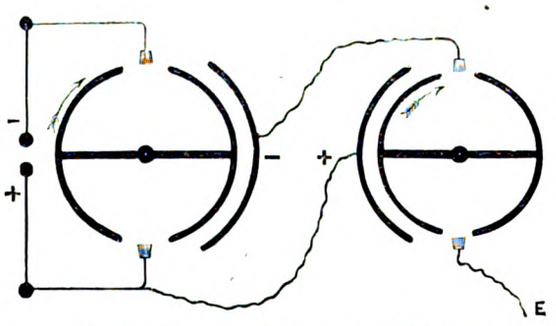

FIG. 9.—Diagram of Toepler's 1865 Machine.

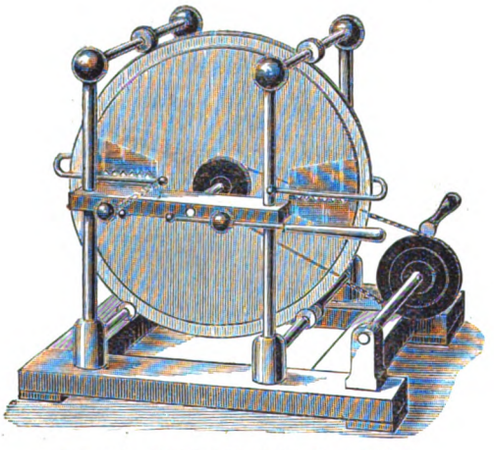

FIG. 10.—Holtz's First Machine (1865).

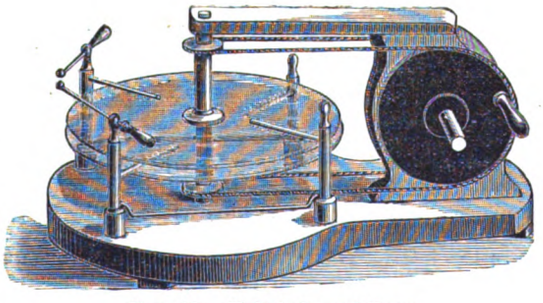

FIG. 11.—Holtz's Second Form.

Holtz, however, proposed another course; instead of interfering with or using up the charges that had accumulated on the field-plates, he proposed to introduce into the middle of the neutralising circuit a discharging apparatus; so that in this first pattern of his machine you actually employ the current in this circuit to give you the sparks. After the machine has been started, and not before, you draw back the discharging rod, and you have a stream of sparks. If that stream once gets broken you must put the knobs of the dischargers together again, in order to make the machine start itself. I mention that fact because it is a defect of the Holtz machine that you must put the discharging parts together before it can go on again. In his later machines Holtz abandoned this device, and added a special "diagonal conductor" to serve as a neutralising circuit, which should always be closed. In this point

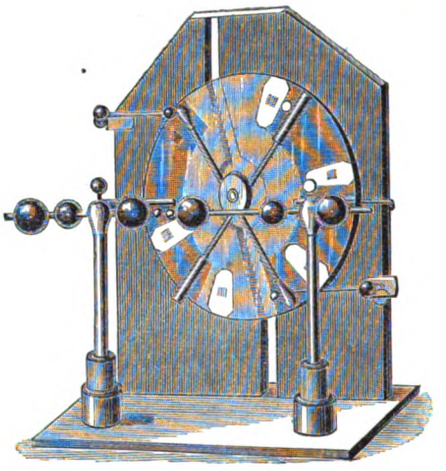

FIG. 12.—Toepler (1880).

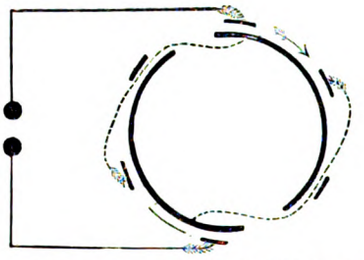

FIG. 13.—Diagram of Toepler's 1882 Machine.

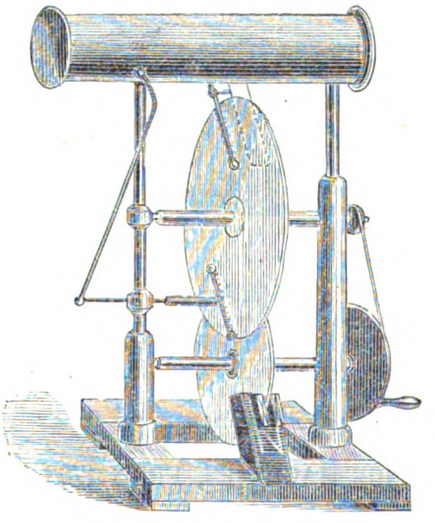

FIG. 14.—Carré (about 1866).

there is a beautiful analogy with the behaviour of dynamo machines. If you use as an external circuit that which contains the exciting coils of the field-magnet, then on breaking the external circuit the machine discharges its magnetism; whereas, if by introducing a shunt you keep the exciting circuit always closed, the complete opening of the external circuit does not discharge the machine. The influence machines with a diagonal conductor may be therefore compared to dynamo machines provided with a shunt circuit. In the further development of this subject we can only follow the most important points; in the complete manuscript of my paper there will

Digitized by Google

be found a full analysis of Holtz's work. Holtz poured forth paper after paper through the pages of Poggendorf's *Annalen*, to which almost every year he contributed something further to the subject of the influence machine, some little paper either on the Leyden jars or on the material for the discs or on the modes of combining them. Holtz's memoirs are very remarkable ; but he came to some rather peculiar conclusions. He came to the conclusion that it was far better not to have metal carriers on the discs, and he also preferred that form of machine in which the glass plates had windows cut into them, which, however, is a form difficult to make and impossible to repair if broken. He devised also another form of machine (Fig. 11), known as the "second kind" of Holtz machine, consisting merely of two circular glass plates, without metal carriers, revolving in an opposite direction, driven from above by strings. The device of two plates going round in opposite directions you will find in the more modern machines, but it was not a success in Holtz's hands. I have never found any one who used one of those machines or even saw one. The description exists and the picture exists, but nothing more. In the meantime, Toepler also was working, and produced the machine shown in Fig. 12. I think the date of this form is about 1879 or 1880. The machine illustrated here is rather a late type of Toepler's machine (Fig. 13). But far earlier than this he was employing carriers on the surface of a disc, those carriers consisting of small metal plates furnished with small projecting metal knobs to be touched by the brushes as they go round ; and in the later forms he, too, attached the neutralising brushes to a special diagonal conductor. In 1866 he draws comparisons between machines constructed with and without metallic carriers, and concludes that those with carriers are more readily self-exciting, are less dependent on the state of the weather, and give a more definite spark-length than machines without metallic carriers. On the other hand, the discharges which they furnish are discontinuous. He, like Holtz, published a great number of papers, an analysis of which will be printed in my paper in the *Journal*. Carré about the same time brought out a machine (Fig. 14) which works partly by friction and partly by induction. I will not trouble you by reading in detail all the references which I have collected respecting this and a number of contemporary forms of machine such as those of Piche, Bertsch, Pouchkoff and others, some of which are of no great importance.

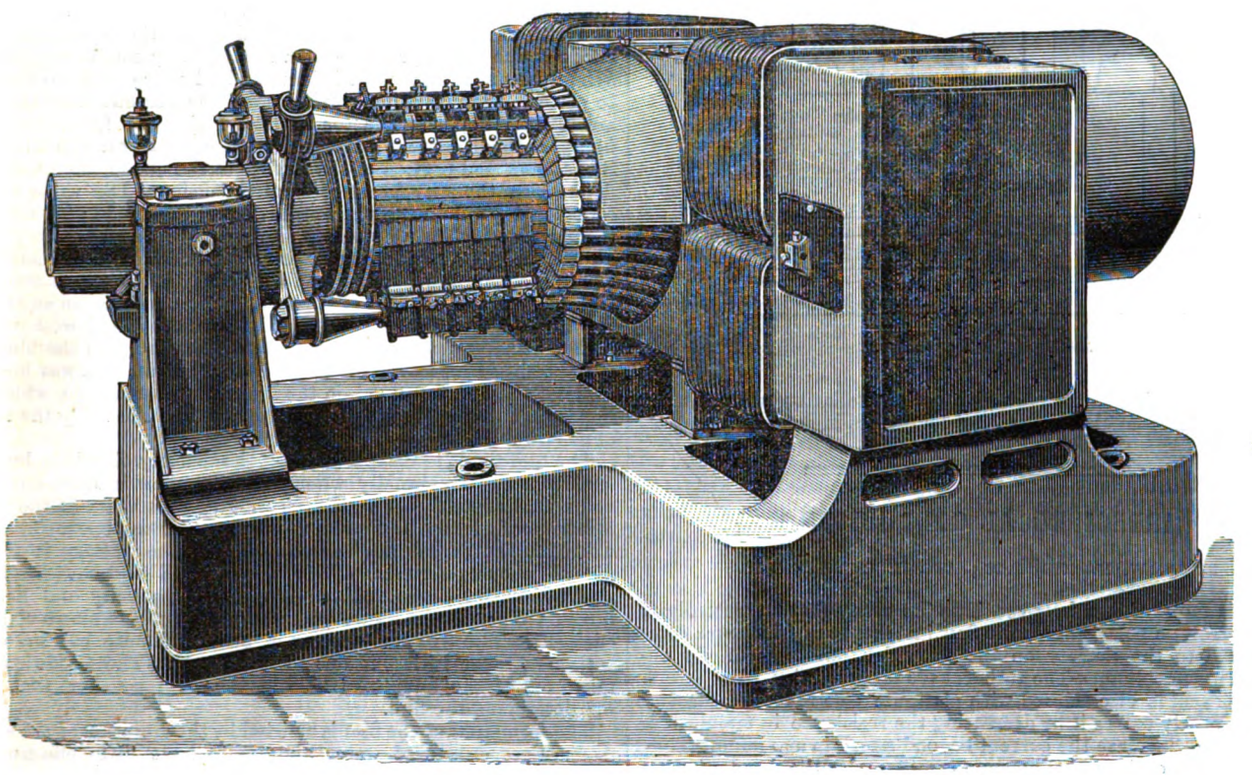
(To be continued.)

Paris.—The Edison Continental Company have started work on their subterranean central station at the Palais Royal. It is intended to instal six 1,000-light Edison dynamos.

MESSRS. ELWELL-PARKER'S DEPOSITING DYNAMO.

The accompanying illustration shows a 4-pole machine, wound for 1,500 amperes at an E.M.F. of 50 volts, the speed being 450 revolutions per minute. The armature is 22in. finished diameter by 20in. in length, of the drum type. There are 80 wires on the circumference, each having a section of 0·2 sq. in., the density of current being 1,880 amperes per square inch of the conductor. The length of active conductor is 1,600in. ; this gives 8in. per volt at a peripheral speed of 2,500 feet per minute. The ratio of the active to the total length of wire on the armature is about 47 per cent. The magnets are plain shunt-wound. Two machines similar to that described have been at work for over six months ; they run day and night, their usual run being about 160 hours per week. There is no sparking with full load.

A machine similar to the above, except that the commutator is shortened, has now been in use for several months driving the Portrush Tramway. This machine is wound for a current of 200 amperes, an E.M.F. of 300 volts with no load, rising to 400 volts with full load, at a speed of 500 revolutions. The armature is the same size as in the depositing machines ; there are 304 wires, the length of active wire being 6,080in. This gives $\left(\frac{6,080}{4 \times 400}\right) \times 3{\cdot}8$in. per volt at a peripheral speed of 2,750ft. The total length of wire on the armature is 13,032in.; thus 46·7 per cent. of the total wire is active.



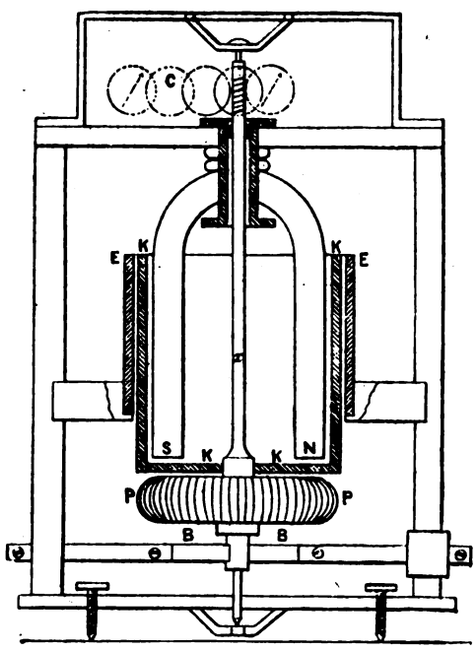
Messrs. Elwell-Parker's Depositing Dynamo.

SIEMENS' COULOMB METER.

In 1887 Dr. Werner Siemens, of Berlin, invented and constructed the very simple motor coulomb meter shown in the accompanying figure, and which has not hitherto been described in our columns. It consists of a Gramme ring, P, fixed to a vertical axle, x, which actuates a system of indicator-dials, C. This ring is placed within the field of the magnet N S, and to the spindle is attached the copper tube K K, surrounded by an iron fixed tube E. The rotary movement is due to a motive couple proportional to the current traversing the Gramme ring and to an opposing couple due to the Foucault currents generated in the copper tube as it revolves round the magnet. There is, therefore, for every value of the current a corresponding speed of rotation. Since the two couples are equally and similarly affected by any change in the magnetisation of N S, the speed of rotation is within certain limits, independent of the magnet. The actual speed is regulated by suit-

Digitized by Google

ably tightening the brushes B B. The apparatus is intended to be placed as a shunt upon the mains, and it is regulated by interposing resistance in its circuit. When the current is weak an error is introduced in the indications. The proportionality is satisfactory except at the start, and Dr. Siemens proposes to correct this defect by using two meters of different sensitiveness arranged in parallel and brought into play by means of a spring electro-magnet, according as the current is strong or weak. The sum of the indications of the two meters would of course give the total quantity of electricity passed through the mains. It is, however, to be feared that the



Siemens' Coulomb Meter.

suggestion of using two meters for each installation will not meet with approval from electric lighting companies in general.

IRRECIPROCAL CONDUCTION.*

BY W. W. H. GEE, B.SC., AND H. HOLDEN, B.SC.

In this Paper the authors continue the researches on electrolysis and electrolytic polarisation, the first instalment of which was communicated to the Society on the 25th Feb., and was briefly abstracted in our columns. The authors have observed that when strong sulphuric acid is electrolysed with platinum electrodes the decomposition nearly ceases if by decreasing the resistance in circuit it is attempted to increase the current beyond a certain maximum. They find that this curious phenomenon comes under the head of what Christiani has called irreciprocal conduction—namely, conduction in which the magnitude of the current is altered when its direction is reversed. The Paper, which is a very elaborate one, opens with a critical and historical sketch. Prof. Erman, of Berlin (Gilbert's *Annalen der Physik*, Vol. XXII., 1806), used the term unipolar conduction, and studied among other cases the unequal conductivity of soap in the direction in which the current had been flowing for some time, and in the opposite direction, respectively. These experiments were subsequently repeated by Ohm, who confirmed Erman's results with regard to soap, but attributed the high resistance at the anode to the production of a film of fatty acid, an explanation which Erman had rejected. Ohm also studied the conductivity of sulphuric acid and of caustic potash; but the results obtained by these early investigators appear to have been due either to what is now known as polarisation, or to chemical transition resistance—namely, a resistance due to the products of electrolysis, according as the electrodes were not oxidisable or otherwise. In 1876 Prof. Christiani published a pamphlet describing a series of researches on the irreciprocal conduction of transient electric currents, in which he studied the effect of using electrodes of unequal size in the electrolysis of various substances, and came to the conclusion that as a rule with low E.M.F. the current is able to pass more easily from the smaller to the larger electrode, and *vice versâ* with high E.M.F., and he comes to the conclusion that this difference remains after the elimination of any effects due to polarisation or to chemical transition resistance. He builds up an elaborate and interesting theory on the results of his experiments, but the present authors show that in various points his methods were so far open to criticism that his results cannot be considered as forming an adequate basis for an elaborate theory; which must therefore, for the present, be considered only as a speculation. Messrs. Gee and Holden give a pretty full account of Christiani's theory and methods of experiments, but for these we must refer our readers to the original Paper.

The authors find that the size of the electrodes is an important factor in determining the stoppage of the currents, and in the electrolysis of strong pure sulphuric acid with one platinum electrode much larger than the other they find that with certain strengths of current the current from the larger to the smaller electrode, which they call the α direction, may be more than a thousand times as great as when the current is reversed (β direction). The obstruction is found to be produced at the anode, for when the insulating condition is once set up no effect is produced by replacing the cathode by a large clean electrode; but if the anode be similarly exchanged the current passes readily. After the production of the insulating condition the resistance in the β direction is found to be much greater than in the α direction, and it continues to increase for some time after the insulating condition is set up. It is found that the polarisation is not abnormal, and, therefore, cannot be a determining factor. It was difficult to obtain more than approximate measurements of the resistance in the insulating condition, as the passage of alternate currents tends to break down the insulation. The authors have come to the conclusion that the resistance at the anode is due to the presence of a film of badly conducting matter. When the size of the anode is increased a larger current is required to produce the insulating condition, so the current density at the anode is an important factor in determining the formation of the film. If C is the minimum current which will form the film, and S the immersed portion of the surface of the anode, then $C/S=\Delta$ is defined as the *film-forming* current density. The value of Δ is found to depend on the previous history of the anode; for example, if the anode has been heated to redness and washed before putting on the current, the film forms with a smaller value of Δ than if the anode has been previously used for electrolysis, either as anode or cathode. When the end of a platinum wire used as an anode was just lowered into the acid, and the film formed by the lowest value of Δ, if the anode was then lowered slowly into the acid the film was found to be formed over the whole wire; but when it was lowered rapidly, the film remained on the lower part for a time, while the upper part was conducting the current, as was shown by the escape of gas from it.

The film tends to disappear when the battery circuit is broken; it disappears very rapidly when the voltameter is short-circuited, and instantaneously when the current is reversed. If the anode is taken out of the liquid and wiped the film disappears at once; when in the liquid and in circuit with the battery it may be moved about or rubbed with a glass rod without being destroyed, except if the rubbing is vigorous, partially and momentarily. When in the liquid a stream of air bubbles blown violently against the film will not destroy it, but a moderate current of air will do so after lifting it out of the liquid. The anode may be taken out of the liquid and held in the air for a short time without destroying the film.

The formation of the film is assisted by the vibration of the anode. A small percentage of water appears to have little effect on the value of Δ, but the authors were unable to obtain the film when the proportion of water exceeded 70 per cent. by volume. When the temperature is increased Δ has to be increased before a film is formed, and the higher the temperature the more rapid is the rate of increase of Δ with the temperature. Attempts were made to obtain the film with dilute acid rendered viscous with glycerine or gelatine, but without success.

The authors endeavoured to obtain the film with carbon electrodes, in which they encountered considerable difficulty from the disintegration of the anode; but ultimately they succeeded in overcoming this difficulty by the use of the coherent carbon filaments used in incandescent electric lamps. When gold was used as the anode and platinum as the cathode the film formed readily, but soon disappeared, and did not reappear until the circuit had been broken. The gold was rapidly destroyed. When the gold wire was first made the cathode and then the anode it was found that the current was either large at first, then decreased rather rapidly to a small value, and ultimately increased again to its former value; or the current was small at first and then made a sudden jump to a high value, at which it remained. The authors were not successful in obtaining the film with phosphoric acid, nitric acid, a mixture of sulphuric and nitric acids, or hydrochloric acid; but in the case of caustic potash a difference was observed in the transition resistance when the current passed in the α and in the β direction respectively.

With benzoate of sodium, an electrolytic deposit of solid benzoic acid with oxygen bubbles entangled in it was formed on the anode

* Abstract of Paper read before the Physical Society on May 26th.

Digitized by Google

when strong currents were used, and the current was thereby stopped; but when the current was weak the oxygen bubbles were able to break through the layer of benzoic acid and prevent the formation of a film.

This behaviour of benzoic acid suggested to the authors that the film formed in the case of sulphuric acid may consist simply of concentrated acid, the specific resistance of H_2SO_4 increasing very rapidly with the degree of concentration.

This appears to be confirmed by the following considerations:—

The rate of concentration at the anode is partially prevented, as pointed out in the Paper by the same authors, previously referred to, by the evolution of oxygen, and also by dilution, the rapidity of which depends on the viscosity and the strength of the acid solution used. With low current densities the concentrated acid would be formed in too small quantity to withstand these two causes tending to disperse it. With great current density the rate of formation of the concentrated acid would overcome the rapidity of the dilution, and the resistance of the layer of acid surrounding the anode might increase so rapidly as to form an insulating film before enough gas had been evolved to cause its destruction, the gas produced becoming entangled in the viscous layer, which, once formed, would not be easily removed by friction, &c. Again, with a current density exceeding a certain limit, the layer would probably be broken up by the escaping gas, for it would be expected that the tendency of the gas to escape would increase at a greater rate than the tendency of the acid to prevent its escape. There ought, therefore, to be an upper limit to the value of Δ, beyond which no film would be produced. The authors have succeeded in discovering such an upper limit, which also explains the sudden jumps in the current strength which were sometimes observed with platinum electrodes in strong sulphuric acid, as when near the upper limit small disturbing causes, such as the heating of the liquid, would cause the disappearance of the film. The authors do not consider that the jumps observed with gold electrodes are to be similarly explained, as gold was found to be dissolved, so that the phenomena would in this case be altogether more complicated. Palladium comes under the same head as gold in this respect, for when used as an anode in moderately strong sulphuric acid it is always found to dissolve. The authors' theory, which they only regard as a provisional one, accounts also for the non-formation of a film in dilute sulphuric acid, for the rate of dilution would be so rapid that a long time would be required for its formation, and thus the oxygen gas might be expected to accumulate with sufficient rapidity to break it down.

The want of success in obtaining a film-formation with the other electrolytes experimented on may probably be attributed to the slower rate of increase of their specific resistance with concentration. It will be of interest to compare the results obtained in this Paper with those obtained by Froeme—an abstract of whose Paper is given in our present issue—with regard to the effect of the size of the platinum electrodes on the degree of polarisation in the electrolysis of dilute sulphuric acid.

ON THE MAXIMUM GALVANIC POLARISATION OF PLATINUM ELECTRODES IN SULPHURIC ACID.

C. Fromme, who has been recently making some experiments with acid varying in concentration from 0·18 to 65 per cent., finds that the relation between polarisation and concentration is most complex in very dilute solutions. With increasing concentration the polarisation at first rises to a maximum, then falls to a minimum, and if the anode is small it attains a second maximum, falls again to a minimum, and finally shows a steady increase as the concentration increases. The author finds that when a larger anode is used there is only one maximum and minimum previous to the steady increase. The material of the vessels used in distilling the water was found to have a marked effect on the amount of polarisation in extremely dilute solutions, due, no doubt, to the presence of glass or metal respectively in the distillate. A small cathode was found to have its surface blackened by the passage of the current, but no sensible alteration was observed when a larger cathode was used.

When both electrodes were small, and the solution very dilute, a yellow deposit was observed on the anode, and when a larger anode was used, a dark yellow coloration appeared after some time. This yellow deposit was unaffected by treatment with concentrated sulphuric acid or *aqua regia*. The author was unable to form any conclusion as to its origin, except that it was not due to any impurity in the solutions.

The black deposit had already been observed by De La Rive and Poggendorff, who showed that it consisted of platinum in a fine state of division, mechanically detached from the cathode. The author found that it could be removed by reversing the current for a sufficiently long time.

In some of the experiments where glass vessels had been used for distillation a greyish brown deposit was observed on the cathode, even when the latter was comparatively large. It was rapidly dissolved by concentrated sulphuric acid, and the author concludes that it consisted of particles of glass.

The amount of the polarisation was found to depend on the size of the electrodes, the size of the anode having a greater influence in the case of dilute solutions, and that of the cathode in stronger solutions.

The principal numerical results obtained by the author were as follows, the E.M.F. being measured in terms of the E.M.F. of a Daniell cell:—

	E.M.F. of polarisation with 0·18 per cent. of acid.	E.M.F. of polarisation with 65 per cent. of acid.
Large anode and large cathode...	1·94	2·43
Large anode and small cathode..	1·45	2·98
Small anode and small cathode..	1·90	4·18
Small anode and large cathode...	1·89	4·31

When the voltameter was traversed by a strong, steady current its resistance was found to diminish as the concentration of the acid increased, reaching a minimum except when a small anode was used, at about the same concentration for which it is found to be a minimum by observations with alternate currents. When the anode was small the resistance had no minimum value, but continued to diminish as the concentration was increased up to the highest value to which the observations extended.—Wiedemann's *Annalen*.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 2nd*, 1888.

The past week has seen a very interesting experiment made as to the relative speed of the telegraph and the long-distance telephone in the transmission of news. The trial originated with the New York *Sun*, which undertook to find out how much news matter could be transmitted to Boston, for the *Herald* there, over the respective wires, in the space of ten minutes. A despatch was chosen which gave an account of a shipwreck and piratical attack in Chinese waters, and hence the matter with its abundance of unfamiliar names was not very easy to handle. At the end of ten minutes time was called, when it was found that the telephone had sent 346 words, while the telegraph had sent 330 words. This appeared to give the advantage to the telephone; but at the other end the tables were turned in favour of the telegraph, from the fact that the telegraph message was delivered all right and in good shape for the printers, while the telephone message was passed over with abbreviations which the "comps." could not understand. The result is interesting, but very far from conclusive, and another trial has been arranged in which the message will be reproduced on the typewriter. There are one or two very material points in favour of the long-distance telephone that may not appear on the surface. In the first place, the telephone message could have been sent through at a very much higher rate of speed than it was, and taken down by a stenographer, leaving the wire clear for more business. In the second place, the telegraph at both ends had to be handled by experts, men whose skill and quickness are the result of long years of training; but with the telephone the message could be sent by anybody, even by the office boy, and could be taken off by an office boy at the other end. Here, of course, is an immense saving in the hire of skilled labour, and perhaps a still greater saving would be effected by the transmission of the despatch by its inditer, without any intermediaries whatever. Now that the typewriter is to be employed as an element in the competition, I think the points in favour of the telephone will come out more clearly. Typewriters have been used since 1883 by telegraphers here in taking copy direct from the wire, but, of course, the rate of receipt has been limited by the sending rate. Now with the telephone, the despatch may be dictated at as high a rate of speed as from 75 to even 85 words a minute, that actually being the speed attained by typewriter experts in this country, while a speed not greatly inferior is common. Probably considerations of this character prompted the New York newspaper to make the test, and I opine that

Digitized by Google

the results will be found of interest to journalists everywhere. It should perhaps be scored against the telephone that where the matter was not first prepared there would be an absence of record.

While this progressive work is in hand a number of the members of the Stock Exchange here are seriously urging their governing committee to step backward, and to adopt a system of pneumatic tubes in place of the telephone for all purposes of communication between brokers "on the floor" and their offices. The objection to the telephone is the publicity necessarily given the messages in sending them. I cannot exactly see the necessity in the case; but the difficulty is said to be experienced, and is said to be felt as well in connection with the telegraph and messenger service. You are already aware of the charges made about tapping the telegraph wires for stockjobbing purposes, and Wall Street is full of stories about tapping the messengers too. One leading broker is said to frustrate the corruption of his messengers by sending orders to buy and sell at the same time; but this, of course, though an exciting way of carrying on one's business, must be highly unsatisfactory. Hence the present movement for the pneumatic tube system, which is said to find many supporters.

While I am on the telephone, I ought to mention the interesting fact that Prof. Alex. G. Bell is about to visit Europe; he leaves for England to-day; his mission is a scientific one. He is to appear before one of your Royal Commissions now investigating the best methods of educating and improving the condition of deaf mutes. This is a subject on which Prof. Bell is probably better informed than any man in America; he has made a persistent, devoted, and exhaustive study of it for years, and has reached a number of very important conclusions. The evidence that he will give to the commission will be of great value, as he has made special preparations for laying before that body the results of his best work and deepest thought.

Among the curiosities of invention must be classed the scheme recently brought to notice by a genius of Norwich, Conn., for securing the safe escape of theatre audiences in case of fire. This inventor proposes to place under each chair in the auditorium a trapdoor connected with a safety shoot. These traps may be sprung singly at the will of the occupant by pressing on electric buttons, or they may be operated at once by electricity from a central point. Now, should the alarm of fire be given, all that the occupier of the seat has to do is to press on his button, and he drops at once out of sight and of danger. In case this process should not prove rapid enough, the manager of the theatre can display his presence of mind by rushing to the main switch-board, throwing the lever, and pricipitating his whole audience, like a ton of coals, into the cellar below. One can easily imagine that the introduction of this device would lead to some very funny spectacles. For instance, a gentleman sitting behind a lady with a high hat might surreptitiously press the button of her chair, and so clear her out of the range of vision; or Edwin Booth, when urging Ophelia to "get her to a nunnery," might be surprised to see his audience suddenly seeking a seclusion not less profound. Of course there would be incidental advantages in the arrangement, such as that of enabling a gentleman in the middle of a row to go out and take a drink without disturbing the people around him. What puzzles me, however, is the working of the device in the galleries. Since these cannot be provided with trapdoors underneath, perhaps the inventor proposes to put trapdoors above and to eject the audience from that part of the house by the release of strong springs.

This is one of the freaks of invention, but we see around us to-day many applications of electricity which strike the public no less comically. Especially is this the case in connection with electric motors and the uses to which they are put. People are still very much amused at motors driving churns, and blacking boots, but they think that the height of absurdity is reached when they see a popular manicure operate by electric motor her various delicate little appliances for buffing, polishing, and cutting finger and toe nails. Such an application I see noted in the electrical papers this week, and I am told that it proves a very attractive feature. Another novel use for the motor is that of operating the cash systems in our large stores. These systems, of which you may perhaps have the counterparts in England, consist of apparatus for communicating between the salespeople and the cashier, over the heads of the customers, expediting greatly the operation known as "shopping." These cash systems are now being worked very successfully by electric motors in some of our best "dry goods stores," and there is reason to believe that in this field, as in so many others where the employment for it was not expected, the motor will find abundance of occupation.

Another galvanometer has just been patented here by Dr. Geyer and an Associate of the Stevens Institute of Technology, based on the heating principle of the electric current. The apparatus is very ingenious. It is composed of a compound arm, or bar, the two arms of which are made of the same metal and are joined at the ends, but are insulated from each other throughout their entire length. The peculiarity of the device lies in the fact that these two arms, although of the same metal, are of different shape and size, and hence are differently heated and expanded by exactly the same current passing in series through each. The apparatus is so arranged that the deflections of the pointer are in direct proportion to the strength of the current passing through the compound bar, and it is noticeable also that the apparatus is independent of effects from the surrounding temperature, as both parts of the bar are equally affected, and to the same extent, by any external changes of temperature. This instrument will serve as well for alternating as direct current.

I have already advised you from time to time of the progress of the movement for patent reform here. The National Electric Light Association, which has taken a special interest in this matter, has arranged to bring two Bills to the attention of Congress: one for releasing American patents from all limitations by similar foreign patents, and the other for establishing a patent court. Both Bills are very well received, and the latter Bill has elicited letters of approval, not only from the Patent Bar Association of Washington, but from the justices of the United States Supreme Court.

A few weeks ago I wrote you to the effect that some of the daily papers here were doing their best to get up a scare on the subject of arc light wires. The best answer to all this superfluous agitation has been given by Mayor Hewitt himself, who comes out boldly and firmly with the statement that the danger is exaggerated. He says that he has investigated the subject, and finds that although there are 7,000 arc lights in use in this city, there have been up to date only four deaths resulting from their use, giving a remarkably small and insignificant percentage for the 9 or 10 years during which the system has been in use. The Mayor says that so small a proportion of accidents is almost unworthy of notice, and I think that most people will agree with him. The manner in which some of the newspapers have handled the subject is highly absurd. One of them sent its "electrician" all round the city to spy out the nakedness of the wires, and whenever he found one that was bare of insulation, he made a report. Nobody knows who this electrician is; perhaps it was the same gentleman who supplied the material to one of our illustrated weekly papers for a sketch which shows all traffic on Broadway stopped on account of a broken wire, which lies in the roadway with its end turned up in the air and touching nothing, but sending out a big shower of sparks like a Fifth of November squib!

SWEDISH NOTES.

(FROM OUR CORRESPONDENT.)

The Gothenburg Electric Company, Limited (Göteborgs elektriska aktiebalag), held a special meeting last week, when the directors made a communication regarding two proposals which they had received for the extension of the company. One proposal was from an English firm, and had several alternative features, but it was considered to give too great advantages to the foreigners at the expense of the Swedish shareholders, and

Digitized by Google

did not meet with much approval. The other proposal was made by the directors of the Gothenburg Engineering Company, and was to the effect that the Gothenburg Electric Company should purchase the central station at Otterhallen. This proposal was favourably received, and the directors were empowered to take the necessary steps. There is every prospect of this amalgamation proving a decided move in the direction of a more general and efficient electric lighting in Gothenburg, which is a town considerably in advance of most others in Scandinavia. The necessary funds will now be raised within the town, and the electric light will in all probability be adopted to a considerable extent. The company has already secured sufficient accommodation for a large central station, which will be immediately proceeded with, and from this station the larger subscribers in the proximity of the harbour can be supplied with light. When the central station at Otterhallen has been connected with the company it is intended to supply from there lights from the best obtainable arc lamps to all squares and places where such light may be decided upon, as well as incandescent lamp light to some neighbouring parts of the town, and by the transformer system also to more distant portions of the town. Through the fact of comparatively cheaper working expenses at larger central stations, the Company will be able to reduce their prices, so that they will be better able to compete with the prices charged for gas and petroleum. It is also the intention to work the central stations through the whole of the twenty-four hours from the end of the approaching summer, and to supply the lamps free of charge to the subscribers.

CORRESPONDENCE.

TELEPHONIC COMMUNICATION WITH SHIPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In compliance with the request in your foot note to Mr. Unbehaun's letter of Feb. 6, 1888 (vide *The Electrician*, No. 512, Vol. XX, p. 484), I now beg to forward a diagram and description of our arrangements for effecting telephonic communication with the mail steamers lying at the Semaphore and Largs Bay anchorage in Gulf St. Vincent.

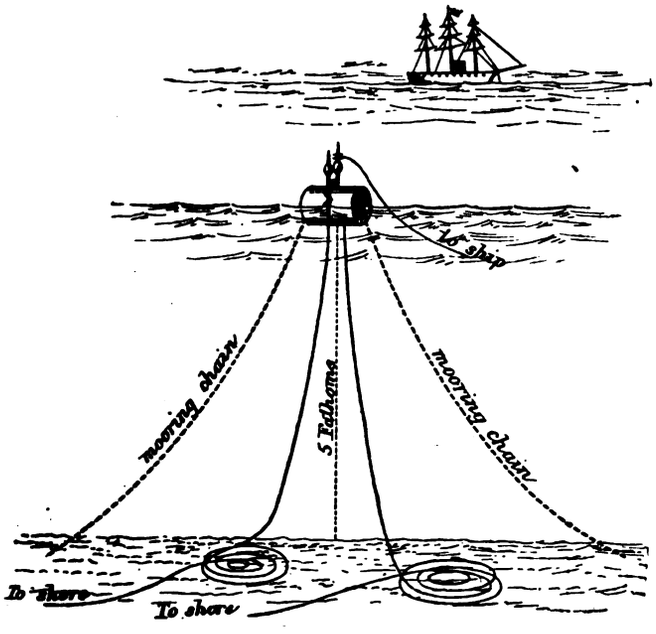


FIG. 1.

At the request of the agents for the Orient Company, Messrs. Stilling and Co., and the agents for the Messageries Maritimes, Messrs. Harrold Brothers, we laid in the early part of 1886 two cables of the B type, manufactured for us by the Telegraph Construction and Maintenance Company, each about 1¼ mile long, from the end of Largs Bay jetty, connected at the sea end with a buoy securely moored in about five fathoms of water.

The mode of fastening the cables to the buoy is shown in Fig. 1. A few coils of slack lie at the bottom below the buoy. The cables are fastened by means of rope, in such a manner as to relieve the cable from friction, to an eye bolt on either side of the buoy, and project about four feet above the surface of the water, the ends being tightly fitted into and connected with Chatterton's compound ebonite insulators (see shaded part of Fig. 2), the core passing through the top of the insulator so as to bring the wire into metallic contact with a pointed or conical copper tube screwed over the top of the insulator, forming a water-tight cap.

The insulated wire (Siemens double G.P. coated, taped and tarred No. 16 copper) is wound on a light reel (Fig. 4), which holds 800 yards of the flexible wire. To the end of the wire is attached a thimble (Fig. 3) of gunmetal, which is bored out to fit about two-thirds down the copper cone. This thimble is so shaped that it can be easily held on the end of a boat-hook, and as the steam launch slowly passes the buoy it is deftly slipped over the cone and the wire paid out to the ship.

FIG. 2.

FIG. 3

To undo it it is merely necessary to lightly tap it with the boat-hook from below, when it slips off.

It is necessary to pay out some slack wire to prevent its breaking when the ship swings with the tide.

The copper cones require an occasional scrubbing with sandpaper, but as a rule the weight of the thimble and the strain of the wire make a very good connection.

The cables at the shore end connect with aerial wires leading to the agent's offices at Port Adelaide. The communication is effective, and is found to be a great convenience to the agents and captains. I may add that the cables were laid

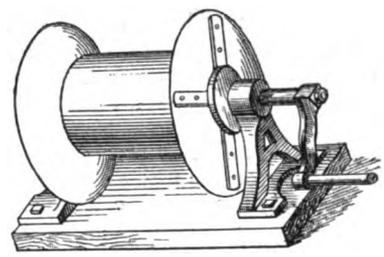

FIG. 4.

during my absence in England, in accordance with arrangements made before I left the colony, and the details for connecting them, &c., were planned by Mr. Unbehaun.

I have the honour to be, Sir,

Your obedient servant,

CHARLES TODD,

Postmaster-General and Superintendent of Telegraphs.

General Post Office, Adelaide, May 7, 1888.

LIGHTNING, INDUCTION IN "BEARER" WIRES, AND OTHER THINGS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 18th ult., Mr. A. P. Trotter asks if it is known whether a lightning discharge is continuous. I do not know, but can offer a little piece of evidence which may possibly assist the judgment of some more capable than I.

Some three years ago, when I was in charge of the East-

Digitized by Google

bourne Central Lighting Station, a thunderstorm occurred one night soon after the lights had been stopped. I took the opportunity of putting a telephone in the line circuit, first without any earth connection and afterwards between one line terminal and earth. In both cases I succeeded in catching the effect of a lightning discharge. It made a curious guttural sound, like the first part of the word "ground," for example, with the "r" rolled very much.

The Eastbourne lines (as everyone knows now, even Mr. Crompton) are underground, so that I must have got an induced effect from currents passing through the earth itself, or from rapid changes of polarity therein. Judging from the time between the flashes and the first thunder the discharges were about a mile and a-half away, while the most distant point of the line was about half that distance in a straight line, and in about the same direction as the storm. It may be noted that the line was a "series" one, and formed a loop enclosing a large area. There was no battery or other source of E.M.F. in the line, so that the effect was not due to any microphonic action started by the thunder. One point struck me at the time, viz., that the sound seemed to commence before I saw the lightning flash. The interval seemed extremely small, but perceptible. However, this may have been an illusion.

Perhaps this experience may suggest a means of investigating some phenomena of lightning discharge without the possible inconveniences incidental to the use of overhead wires during thunderstorms.

In Mr. Kenneth Mackenzie's Paper on "Distribution by means of Secondary Generators" there is a little passage which I do not understand. I stumbled over it in *The Electrician* report, but waited for the *Journal* of the Society to see whether it was repeated in the official report. It is so repeated, and it consists of the paragraph commencing on the last line of page 1ϟ1 of No. 71 of the Society's *Journal*, and filling about one-third of the next page.

Mr. Mackenzie says that when "bearers" are used, and their ends left open, so that no current can flow through them, a counter-electromotive force is generated, which retards that in the main wires; and, further, that earthing the ends of the bearers through lightning arresters obviates this retardation. Mr. Mackenzie does not explain the *modus operandi* of the disease or the remedy, and I am really curious to know what the effect is.

Obviously, if the bearer ends are insulated no current can flow in them, and therefore no effect can be produced upon the primary or main wires. The analogy with a series transformer is not on all fours, because the transformer has a magnetic circuit of iron.

It is perfectly true that if the bearer circuit were closed the apparent self-induction of the mains would be diminished on account of the current in the bearer wires; but there would then be some loss of energy corresponding to that current. Mr. Mackenzie does not desire this, of course.

Besides, "closing the bearer circuit through lightning protectors" is not closing it at all to such E.M.F.'s as it will have generated in it, and one cannot see what difference it can make.

Briefly, then, the presence of the insulated bearer wire can make no appreciable difference to the self-induction of the mains, though a very small increase may be produced if the bearer is of iron. A closed bearer circuit means an induced current in it, with, of course, a loss of energy, and a smaller self-induction in the mains. And, lastly, earthing the bearers through lightning conductors—presuming that the latter are made, as usual, with L and E terminals well insulated from each other—can make no difference.

Then if the effect is laid off to static induction (Mr. Mackenzie offers no opinion) the same thing occurs. The insulated bearers can have no appreciable effect upon the capacity of the line. Closing the bearer circuit increases the capacity, and so causes some loss (very small, no doubt); and closing the bearer circuit through lightning arresters is about the same as leaving it open.

I, for one, shall be glad to know what the effect really is which Mr. Mackenzie has observed, and some explanation of its cause and cure.

By the way, there seems to be no particular loss in underground conductors on the parallel alternation system, even when the wires are in iron tubes (as at Eastbourne, for example). It is doubtful whether it is worth while to use concentric cable for underground work, but of course both wires must be in the same tube and tolerably close together.

And while on this point, I must take the opportunity of stating—not without a fair amount of experience—that there is no difficulty now in laying a cable underground to carry 2,000 volts E.M.F. for an indefinite period. You must buy good cable, of course, and must have the joints so made that the minute cracks spoken of by Mr. Crompton do not appear. This, again, is only a matter of care, experience and good materials.

Several plans have been lately proposed to guard against contacts between the primary and secondary wires in transformers, and perhaps another is superfluous. A vacuum tube, like those used for lightning arresters on cables, put between the secondary coil and earth, with an electromagnet in the the circuit, might be used to short-circuit the mains whenever the tension between earth and the secondary exceeded a certain amount. There is, however, one weakness incident to all these "relay" plans, as they may be called, viz., that if the contact between the two circuits occurs about midway in the primary, the potential difference between that point and earth may be very small. The earthed sheet of metal between the two coils seems the best device. In the Lowrie-Hall transformer, it may be noted, the danger contact is very slight, and earthing the iron core in such a transformer is all that is necessary for safety.

I ought to apologise for a somewhat rambling letter; but it is a relief to write "shop" when in an out-of-the-way place like this, where there is no one to talk "shop" to.

This out-of-the-way place, by the way, has some 500 telephone subscribers amongst its 140,000 inhabitants, a considerably larger proportion than in London; and the demand for electric light from the central station recently opened is very promising, so that additional machinery is already necessary.—Yours, &c.,

HENRY M. SAYERS.

Rua du Carvathosa 79, Oporto, June 6th, 1888.

THUNDERSTORMS AND LIGHTNING ACCIDENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the season of thunderstorms and lightning accidents is now approaching, I hope you will kindly allow me to make known through your columns the fact that, in the interest of science, the Institute of Medical Electricity is very desirous of obtaining authentic information concerning lightning accidents, whether fatal or otherwise.

I should therefore esteem it a favour if some of the many friends of humanity among your readers will assist us to investigate these phenomena by sending me such particulars of accidents of this nature as they may have personal or reliable knowledge of, as soon after they occur as possible.

Of course electrical and physiological details are what we most require, but reliable general information is often very valuable, and will be gratefully received.—Yours, &c.,

H. NEWMAN LAWRENCE, A.S.T.E. and E.,
Electrician to the Institute of Medical Electricity.

24, Regent-street, London, S.W.

THE ELECTROLYSIS OF MERCURY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter of Mr. Lowrie-Hall on the "Electrolysis of Mercury" in last week's issue recalls some phenomena of interest in the use of mercury electrodes which may not have been observed by some of your readers, and which will, perhaps, explain the formation of the insoluble salt by currents in one direction, which is not reduced by those in the reverse direction.

I think it doubtful, however, that the arrangement in question will form an accurate current meter, as the results of decomposition will disappear to a greater extent with the enlarge-

Digitized by Google

ment of the surfaces of the electrodes, or with the diminution of the volume of current passing.

When a surface of pure mercury in sulphuric acid is employed as the cathode in electrolysis, the mercury absorbs a considerable quantity of hydrogen. If, when in this condition a compact pinch of bisulphate of mercury be dropped upon it, decomposition takes place; the surface of salt resting on the metal yields metallic mercury and sulphuric acid. As soon as the hydrogen immediately beneath the sulphate is absorbed the latter will move to a fresh position, until it has gracefully skated over the whole surface, and if the quantity be smaller than that which is necessary to depolarise the electrode it will entirely disappear.

A battery consisting of an amalgamated zinc plate, suspended in sulphuric acid solution above an electrode of mercury, upon which a layer of fine dry bi-sulphate of mercury has been evenly sprinkled, exhibits some remarkable phenomena when the circuit is closed.

A perfect storm arises, and in a glass vessel the mercury is seen to be violently agitated, and if the shape of the bottom of the glass is such that there is something like a sloping beach, ponderous looking little waves roll up resembling those of the sea. At the same time, clouds and whirlwinds are formed above, gradually increasing, until the whole is completely obscured.

The sulphate of mercury may be formed for this purpose in the cell itself by electrolysis.

The action is of course attended with the disengagement of a considerable quantity of electricity, and I think the surface agitation is due to the diminished cohesion of the molecules of metal when charged with hydrogen.

The changing tension of the mercurial surface is beautifully shown by opening and closing the battery circuit rapidly.

To avoid failure in using this arrangement as a secondary or primary battery the solution must always be strongly acid, or the bisulphate will be reduced to a subsalt, which is the cause of what Du Moncel calls the unaccountable failure to which at times the Marié-Davy battery is subject.—Yours, &c.,

F. HIGGINS.

17, Cornhill, E.C., June 13th, 1888.

A NEW INSULATOR FOR DELICATE APPARATUS.

M. Palmieri, of the observatory on Mount Vesuvius, possesses an electrometer which, says *La Lumière Electrique*, is superior to all other instruments of the same kind. "It is so perfect," said M. Mascart at the Meteorological Congress, held at Rome, "that it could be used to standardise every other instrument in the whole world." The superiority of this remarkable instrument is held to be due to the good qualities of the insulating material which was used in its construction: and we are happy to be able to make known to the electrical world the constituents of so admirable an insulating substance. It is a mastic composed of two parts of Greek pitch (*poix grecque*) and one part of calcined plaster (of Paris). The plaster is made from pure gypsum, which is raised to a high temperature in order to drive off one half of the water of crystallisation, and is then thrown while hot into a bath of cold water. The mastic is formed by mixing these ingredients while hot, and it yields a viscous pasty substance, which can readily be moulded into any required form. It possesses the insulating properties of ebonite, but is much more plastic. In colour it resembles dark amber. Its great advantage for electrical purposes arises from a characteristic property, by which the insulation resistance does not decrease with rise of temperature, and it is also said to be even unaffected by moisture. The former property is certainly a very valuable one, so also would be the latter, although we confess to some doubt of the accuracy of the statement, seeing that the effect of moisture is to cause leakage over the *surface*. However, the responsibility for the entire paragraph must rest with our esteemed contemporary, *La Lumière Electrique*.

THE ELECTRIC LIGHT SCHEME IN EXETER.

TENDERS INVITED.

A special meeting of the Exeter Town Council was held on June 6th to consider the report of a special committee on the electric lighting of the city.

At the last meeting of the Council a report was presented from the committee, but the Council broke up for want of a quorum without coming to any decision. The mayor convened this meeting at the request of 25 members of the Council, to especially consider this report. The report presented at the last meeting recommended that tenders be invited by advertisement for lighting a specified area by means of the electric light, subject to the terms of the specification prepared by the surveyor, and to the stipulations of the Board of Trade.

Mr. TOWNSEND, in moving the adoption of the report, thought that the Council were persuaded already that the question was of so much importance that the advocacy of electric lighting did not require much speechifying. They were anxious that nothing should be done to the detriment of the existing Company which was at present lighting the city with gas, but seeing that this question was of so much importance and that the citizens demanded a better light the Council were in duty bound to take it up. In doing so they could not do better than adopt the principle which this committee recommended, that tenders should be issued for contracts. The resolution did not bind them to any particular company or the scheme of any particular engineer, but they were bound in honour to accept the best tenders whoever they might come from. He wished it to be understood that he had no particular interest in any company that had been started. He had been charged with having some motive, and with holding a retainer on behalf of one company. The only brief he held was one from the ratepayers to get a better and cheaper light. The committee recommended that the tenders should be in two forms, one for overhead and the other for underground wires, so that the Council might see the difference in the cost and the comparative position of the two sets of wires. Further, the tenders were to be advertised for in the same form and with the restrictions that the Board of Trade required, with the addition of some safeguards which were thought by the surveyor to be required in the case of a city like Exeter. This would involve a little expense. The committee had obtained a great deal of information on the subject, but since they had met other information had reached him, not from persons interested on either side but from an official source. The information was from the Town Clerk of Bath. One of the questions asked by the Corporation of Bath before they decided to adopt electricity was, did they find the electric light a success? Taunton said, Yes; Waterford said, Yes; Eastbourne said, Yes; and Leamington said, Yes, in public buildings. The reason why the light had not been so successful in the streets of Leamington was because there the system had been adopted of laying the wires underground. He read the figures obtained from these towns, showing that the cost of electricity was somewhat in excess of gas; but he went on to say that seeing the strides which electricity was making every effort would be made to keep the cost down. If the cost of electricity was much more than gas they would not find him a supporter of the scheme, but if it could be adopted at a reasonable cost he thought they would be justified in trying it. They were not going to interfere with the Gas Company to any extent. They only said to them, if you are a public company you must be able to compete with the inventions of the age, and you suit your supply according to the requirements of the public. It was their duty as a Council to encourage competition in the hope and with the view that the public would eventually get the benefit of it.

Mr. BALE seconded the motion.

Mr. DAW asked the Town Clerk as a point of law, if tenders were advertised for, could the Council do anything upon that? As he read the law, a company supplying the light must either get an Act of Parliament or a license from the Board of Trade, or a provisional order.

The TOWN CLERK said that was the law with regard to the manufacture of this light.

Mr. DAW said a company could not carry out their contract without going to the Board of Trade.

The TOWN CLERK replied that persons who tendered must be duly authorised to supply this particular area.

Mr. DUNN said his objection was that the Committee was appointed for the purpose of obtaining information as regarded the terms upon which electricity could be obtained. He had been of opinion in the committee, as he was now, that the issuing of a notice for tenders was not the best means of obtaining what they required. Information had been obtained since the committee met, and they ought to have been put in possession of it, but instead of that, Mr. Townsend hugged it up all to himself and made use of it for the first time that day.

The MAYOR said it would be remembered that Mr. Massingham handed it round when he attended a meeting of the Council.

Mr. WIPPELL argued that the system of tendering was absolutely necessary if they were going to arrive at any definite conclusion, and he thought it was absolutely necessary that all the tenders should be upon exactly the same specification.

Mr. WILSON said they had come to a conclusion in committee that a certain specified area should be lighted, and that for that area they should issue an advertisement for tenders.

Mr. BOWDEN moved as an amendment that no further steps be taken until each member of the Council had been supplied with a printed copy of the specifications.

Digitized by Google

Mr. BECKIT seconded.

Mr. DAW said he did not see how, then, they could invite tenders upon specifications which had not been approved. That was a very strange way of doing business.

Mr. WIPPELL inquired whether the committee were in possession of the specifications?

The MAYOR distinctly understood from the chairman of the committee and other speakers that the specifications had been before the committee, and that they recommended that tenders be invited upon those specifications.

Mr. DAW: Since the specifications were before the committee on the 19th May, have they been altered in any particular?

The TOWN CLERK replied in the negative.

The SURVEYOR said that although the specifications had been before the committee and approved by them, they were referred to the town clerk to see the legal aspect of the case.

The MAYOR said as a matter of order he should rule that by recommending that tenders be invited upon certain specifications the committee thereby approved of those specifications. Otherwise it was child's play.

The SURVEYOR said the point referred to the town clerk was as to the liability of the Corporation.

The MAYOR pointed out that it was quite open to the Council if they adopted that report to give any instructions they thought proper to the committee or the town clerk, or to both, with reference to these specifications.

Mr. ANDREW said he did not like to vote against the report, but he was not strongly in favour of it because he did not think that the method proposed to be adopted was the best one. They were not acting in good faith towards the parties from whom they asked tenders by not having first made up their minds whether they would accept any. That was not the most honourable way of getting information, and there were other ways of getting it besides giving parties a lot of perhaps unnecessary trouble. If the information obtained by Mr. Townsend had been laid before the committee it would have been better. But the main point was whether the expense of obtaining what they believed to be a better illuminant would be greater. Everybody conceded to electricity superiority in lighting over gas, and if there was anything like an equality of cost he should not hesitate for a moment to vote for the report; but they had heard that those places which had been lit by electricity paid nearly double what it had cost them for gas. He did not think that in such a case the Council would make the change proposed. There was no kind of standing-still about the science of electricity, and he thought they were a little too soon in their inquiries. He should like the matter to go back to the committee and see if they could not furnish them with some better information, although he did not say he should vote against the resolution if it were pressed. It would be considered a very unreasonable thing for a private gentleman to send out tenders for the erection of a villa, if it were known that he only wanted to obtain information of the cost of erecting a villa.

Mr. POPE: It is constantly done.

Mr. DOMVILLE said as to whether tendering was the best method of getting the information they wanted he was bound to say that he thought it was the only method.

Mr. ANDREW said he was sorry to hear it.

Mr. DOMVILLE said Exeter was so situated, as some of the electricians informed them, that the citizens were in a better position for obtaining motive power than almost any other city in the country. They had water-power of almost unlimited extent at their doors, and it was necessary that they should know whether they could adapt that water power or not as a motive power for the electric light. At that moment electric lighting companies were looking out, not only upon Exeter, but everywhere else, for an opportunity of exercising their powers, and probably several companies were willing to tender if they knew that this Council had taken up the question seriously. He did not think that the Council would be taking any unfair advantage of any company if they asked them to tender to light a portion of the city on the understanding, tacit or expressed, that if they could offer to do it at anything like the price of gas, the Council would be willing to entertain their offer. He hoped they would not be led aside by anybody who was interested in preserving the rights of any existing companies in the city.

Mr. BOWDEN protested against the idea that there was any endeavour to get rid of this question by a side wind. They knew the messes they had got into in days gone by by adopting measures that they did not understand, and he was not prepared to give a vote on this question until he knew what he was voting for.

Mr. FORCE agreed that tendering was the best means of getting at the prices, but he feared that after the observations which had been made that position was seriously damaged. If twenty persons had intended sending in tenders, probably that number would be reduced to ten when it became known that the Council wanted the tenders only to see the prices, with the option of accepting any one of them or not.

A division then took place upon the amendment, which was that printed copies of the specification should be printed and circulated before tenders were invited. The amendment having been declared to be lost, the report was adopted.

Mr. DAW moved, and Mr. WIPPELL seconded, that a period of three months should be allowed to lapse before the tenders were sent in.

Mr. WREFORD did not know whether this delay was proposed in order to give the Exeter Gas Company the chance of tendering for the electric light.

Mr. WILSON said he did not see why the gas company should not supply the new light.

Mr. BOWDEN protested against the jibes which had been directed against Mr. Daw. It was true that Mr. Daw was solicitor to the Gas Company, but there were members present who belonged to the Electric Light Company, and who were waiting anxiously for the decision of the Council. He thought that they should not hastily commit themselves to a course which they might eventually regret that they had adopted.

Mr. BLACKBURN said if the Council waited three months for tenders they would not have any electric light this year, and he thought six weeks would be ample time.

Mr. WREFORD moved, and Mr. TOWNSEND seconded, as an amendment, that the time be two months.

Mr. DAW asked why they should hurry this on in the interest of one particular company, because that was what it was? The existing Electric Light Company had been maturing their plans for months, and probably they had got the tenders in their pockets now. He should ask the citizens seriously to consider whether three months was too long a period.

Mr. POPE said the electric lighting companies were prepared at the shortest notice to submit tenders, and did not want three months.

On a division the resolution of three months was carried by a majority of one. It was agreed that tenders should be sent in not earlier than the 22nd September.

LEGAL INTELLIGENCE.

United Telephone Company v. Tasker, Son and Co.

In the Chancery Division of the High Court of Justice, on Friday last, the case of the United Telephone Company *versus* Tasker, Son and Co. came before Mr. Justice Kay.

This was a motion by the plaintiffs for an interim injunction to restrain the defendants, who are the proprietors of a telephone exchange at Sheffield, from infringing the plaintiffs' patent for telephone transmitters and receivers.

Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Micklem appeared for the plaintiffs; and Mr. Ince, Q.C., and Mr. Bousfield for the defendants.

Mr. JUSTICE KAY: I come to my judgment in this case without the least hesitation. The defendants admit that they are using telephones which are an infringement of the patent dated in 1876, and which belong now to the plaintiffs. The making of these telephones would be an infringement, and clearly that is a continuing wrong. Every day they use them they are infringing the patent. They admit the user, and they admit the telephones are the telephones which are infringements of that patent; but they attempt to justify in this way—they say that the defendants have formed an Exchange Company in Sheffield; they did that at the instance of the plaintiffs or their predecessors in title and by agreement with them. That agreement they say the plaintiffs now refuse to carry out, and they say, "They refused to supply us with any telephones at all; therefore we have for the preservation of our business made these telephones, which we admit are infringements, and we are now using them." Obviously that is not a justification. Of course that will not do for a moment. I put the case during the argument of an agreement by a man for value that he would out of a balance then at his banker's make a certain payment, and a flagrant breach of that agreement, would that authorise the person to whom the payment was to be made forging a cheque on the bank? Really that is a very analogous case. The infringement of a patent because another contract has not been carried out by the patentee is a taking of the law into your own hands which of course cannot be listened to for a moment. Because a contract has been broken, a person who alleges that contract to be broken takes upon himself to infringe the patent of the other party to the contract, of course could be no justification in the world. At the same time it is suggested that there is considerable question as to whether the contract under which the Exchange Company of Sheffield has been formed (perhaps I am wrong in calling it a company, but I will say the exchange in Sheffield has been formed) has been broken in a flagrant manner by the plaintiff company. On the other hand it is denied. I cannot determine the rights of that now. It is said the plaintiffs have set up a rival exchange in Sheffield, and, of course, it is possible. I do not say it is so at all, but it might be suggested that the main purpose and object of this application now is to destroy the one company and encourage the other. I do not say it is so, but that might be suggested. In order to prevent any suggestion of that kind I intimated to the plaintiffs that it would be a fair thing that until the trial of this action they should replace the telephones, which the injunction I am now about to grant will prevent the defendants from using or selling or disposing of in any way, by telephones of their own, which they may either lend or let for hire, or sell or supply on any terms they please, the object being that the business which the defendants have set up by this exchange in Sheffield should not by this order be brought to an end or be very seriously interfered with. I think that will be quite fair. Of course, there will be the usual undertaking as to damages. Upon those terms I now grant the injunction to prevent the defendants, their servants and agents, from making use, selling, or otherwise disposing of any telephones which are an infringement of the plaintiffs' patent, the plaintiffs undertaking to supply to the defendants upon usual terms as to costs, but otherwise either by way of loan, or sale, or letting at their pleasure, so many telephones as this order will prevent the defendants from using. There will be the usual undertaking in damages. This is, of course, till trial of action or further order.

Digitized by Google

Mr. ASTON: That does not extend to their laying down any extension of their system, or introducing a new system.

Mr. JUSTICE KAY: I have limited it by the number of telephones which this prevents them using.

Mr. ASTON: Now using.

Mr. JUSTICE KAY: Yes.

Crampton v. Patent Investment Company (Limited).

In this action, which has occupied Mr. Justice Field, without a jury, for four or five days, the plaintiff, who is the patentee of certain improvements in and relating to electric bells and alarm clocks and apparatus to be used in connection therewith, sued the defendants, under section 32 of 46 and 47 Vic., cap. 57, to recover damages from them for having, in contravention of that section, threatened him with "legal proceedings, or liability in respect of any alleged manufacture, use, sale, or purchase" of a certain invention which he (the plaintiff) claimed in a certain electrical bell which he was at the time manufacturing and selling. The plaintiff pleaded that he had never used the defendants' invention as alleged, nor was his bell, in fact, an infringement upon the defendants' patent, or of any legal rights of the defendants. The plaintiff further alleged that the defendants' patent was bad for these reasons *inter alia*—(*a*) that the defendants were not the true and first inventors; (*b*) want of novelty; (*c*) non-utility; (*d*) ambiguity in specification and variation in provisional and final specification; (*e*) anticipation. The plaintiff further pleaded that the defendants would continue their threats until restrained by injunction; that the defendants had commenced an action against the plaintiff for infringement of their letters patent in October, 1886, but discontinued the same by notice in August, 1887. The defendants admitted that they had threatened the plaintiff and Messrs. Swete and Main (agents of the plaintiff) with legal proceedings for infringement, but denied that such threats were wrongful, and did not admit that the electric bells made by the plaintiff were made according to his alleged invention; that their patent was good and valid; that the bells which the plaintiff was manufacturing, and of which they complained, were an infringement of their legal rights; that in commencing their proceedings against the present plaintiff in the former action they had acted *bonâ fide*, without malice, and with reasonable and probable cause. On these pleas issue was joined.

Mr. E. E. Jenkins appeared for the plaintiff; and Mr. Rogers W. Wallace was for the defendants.

The evidence and arguments were chiefly of a technical character, and at the conclusion of the case

Mr. JUSTICE FIELD said that it had been conducted by both counsel with such skill and care that he was, notwithstanding its highly technical nature, in a position to decide it at once. Having pointed out that the object of the Legislature in enacting Section 32 of the Patent Law Amendment Act—under which this action was brought—was to protect deserving patentees from being harassed and oppressed by threats and vexatious actions by persons wrongfully claiming right to use their inventions, he said that the section gave the right to any such aggrieved person of recovering damages in an action against the person or persons so threatening him. It was that remedy which Mr. Christopher Crampton here wished to enforce. It was clear, his lordship observed, that the plaintiff claimed to be the inventor of Jensen's bell, and also that they had threatened him (Crampton) with legal proceedings, and, indeed, actually commenced an action against him (the present plaintiff) for infringement of their Jensen's bell. That action, however, was discontinued on terms which it was not necessary to refer to. It had been argued that the defendants had not used any threats within the true meaning of the section. Even if there was no authority upon that point he would have decided it, as he now did, in the defendants' favour. Now, were these threats justifiable? That depended upon whether or not the defendants had any legal rights to what they claimed. Referring to the Jensen bell (the defendants' patent) his Lordship said there could be no doubt that it was a very great improvement, and that the whole combination adopted by Jensen was of great utility, and proper subject matter for a patent. That being so, it seemed clear that the defendants, who were now admitted to be the patentees of Jensen's bell, had *primâ facie* legal rights in their patent. Referring to the mechanism of the different bells, the learned judge said it was obvious that Crampton and Jensen's bells were substantially the same, producing the same results by the same means; and Jensen's being the senior in date, Crampton's was, he said, an infringement of Jensen's *primâ facie* legal rights. But the plaintiff had attacked this *primâ facie* right, alleging on various grounds that their (the defendants') patent was invalid. First, it was said there was variation in the specifications. His lordship held that there was substantially none. Second, as to anticipation, he referred to the case of Cornish *v.* Kean (1 Web., R. 507) on that point, and held that there was not sufficient proof of anticipation. He also held that the defendants' patent was useful, new, and proper subject matter for a patent, and finally gave judgment for the defendants on the usual terms.

Avery v. The National Company for the Distribution of Electricity by Secondary Generators.

This was an application made on the 8th inst., in the Queen's Bench Division, before Mr. Baron Huddleston and Mr. Justice Charles, for a new trial of the case, which was tried on 10th April, resulting in a verdict for the defendant company. Judgment was again given for the company, leave for a fresh trial being refused.

PATENT RECORD.

COMPANIES' MEETINGS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The seventh annual ordinary general meeting of this Company was held at the Terminus Hotel, Cannon-street, on the 7th inst., under the presidency of Mr. C. L. W. FitzGerald.

The Secretary (Mr. CHARLES CURTOYS) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, the report which we have laid before you, as you will see by turning to the figures, shows available as the profit of the year the sum of £10,788. 7s. 4d., which, with the balance we brought forward from last year, of £1,695. 18s. 5d. amounts to the sum of £12,484. 5s. 9d. As you are aware, we have already paid an interim dividend at the rate of 5 per cent., and we now propose that we should write off the machinery and plant and the furniture the sum of £541. 6s. 3d., and also pursue the policy which we have always carried out—that of writing down the values of things to a certain extent. We propose to write a further sum of £2,000 off the item on the credit side of the balance-sheet under the head of "investments in telephone companies"—that is, off our shares in the Edison-Gower-Bell Telephone Company. We hold in that company 20,000 Preference shares of £1 each, and 15,000 Ordinary shares of £1 each. We have now reduced that item from £25,000 to £18,000. I will now go back to the expenses. The ordinary expenses for the year amount to, in round figures, about £200 less than those of last year. The legal expenses are a little less. We then come to an item which I do not like very much—"arrears of fees and special remuneration, Colonel Gouraud and costs—£952. 1s. 10d." That is in reality an item which should have been paid in the year 1883-1884 out of the profits that Colonel Gouraud had made himself; but, unfortunately, at that time, when Colonel Gouraud was chairman, there was not the money to pay the fees with. We have had to pay the fees, Colonel Gouraud having brought an action against the Board for those fees which were in arrear. Although we (the Company) had imagined that Colonel Gouraud, having sent round a circular to all the shareholders stating that he had resigned his fees, when it came to the trial the Court held that that circular was not sufficient evidence of Colonel Gouraud relinquishing his fees, and consequently they gave their decision against the Company. I now go a little lower, and there you find the sum of £175 which we have spent on the Belgian patents. We have up to this time spent £375 on that particular head, and of course you must not look on that money as lost yet, as that money is for the legal expenses of this patent trial, which we hope will bring this Company in a large sum of money should it result favourably. It is a very difficult matter for any one to say that it will result favourably; but so far, it has gone favourably. We then come to an item, "Return of capital," £139. 3s. 10d., which you will remember, was in return of capital last year. We have then a sum reserved for a claim in dispute and bad debts, and that claim has been settled for £100, and £20 the cost of the arbitration. We are therefore rather to the good there. I now come to the balance-sheet. Against the item capital expenditure, goodwill, patent rights, &c., stands the sum of £75,436. We have not deemed it necessary to write anything more off that this year, for the reason that we wrote off such a very large sum last year. Then comes "agency account, Austria." The sum invested in telephone exchanges, patent rights, &c., amounts in round figures to £127,245. That is, as you see, "contra'd" on the other side. It is of no importance in this balance-sheet, but I shall have something more to say on this head when we come to the extraordinary general meeting. Our plant and machinery now stands, after we have written off the sum we propose, at £4,740. 12s. We have written down that plant by about, roughly, £2,500, and I can safely say this—that the plant to-day is in the most efficient state, and that we go on improving our plant and at the same time write down its value. The stock of instruments, you will observe, is rather more, about £1,000; that is caused by our having taken over the stores of our late contractor. I do not know that I need make any further remarks about these other items. I have already spoken about the Edison-Gower-Bell Telephone Company. I will now go to the debit side, and there you see an item of sundry creditors and credit balances, £2,025. 7s. 10d. All this is pretty well paid off. I think we only owe really about £300. I think that that is fairly satisfactory. As you see by our Report, after writing off these various sums, we propose to pay you a further dividend of £2. 17s. per cent., which will make a total dividend of £5. 7s. per cent. I have already spoken to you on the subject of Colonel Gouraud's action for payment of his fees, and I regret to state that he has now, after waiting the whole four years, thought fit to commence an action against the Committee of Investigation on the ground that the reports published to you are libels on him. We are advised by our solicitor that those reports undoubtedly are privileged reports, and all I can say, as Chairman of that Committee, is that nothing could be further from our thoughts than libelling Colonel Gouraud. There is no object in libelling him. What we did try to do was to show from the minutes what we found there to the shareholders, and we put that in print. Whether Colonel Gouraud will proceed with the action I cannot tell. I have already spoken to you on the subject of the Edison-Gower-Bell patent action in Belgium. We none of us can say how that will end, but our solicitor is decidedly of opinion that we at all events have a very good case, having the same patent, which is the patent in England that governs all the telephone wires about us. I now come to a paragraph alluding to the Portuguese business. The Edison-Gower-Bell business in Portugal has been sold to a company called the Anglo-Portuguese Telephone Company, which has already issued one report, and I may say that it is of a decidedly favourable nature. I trust that this Anglo-Portuguese business, which has already a very considerable income, will some day or other return some dividend to the Edison-Gower-Bell Company, as they hold the shares, and that that Company will hand some of the profit on to us. The next paragraph relates to the manufacture of telephones. As you are aware, when we, the present Board, took over this business, there was a contractor. He was a very able man indeed, and undoubtedly he knew his business very thoroughly. That has gone on for four years, and we, on certain occurrences, determined that it would be for your interest that we should undertake the manufacture of telephones for ourselves. I am fortunate, I think, in now being able to say that my studies under this gentleman, the contractor, and my having been daily at the works, have enabled me to master the manufacture of these telephones sufficiently to be able to say that I can undertake the management of your business. I may say that since the contract was terminated, everything in connection with the work has gone on satisfactorily. I find no difficulty in it, and I trust—as I think any one must see—that we ought to make more profit than if we employed a third party who contracted to make the instruments at a fixed price. The next paragraph is one which I am sure the shareholders will be pleased to see—that is that all the telephone interests, the United Company and our Company—are working in harmony together, and no doubt, should this amalgamation alluded to in the Report take place—of which I think there is every probability—we shall see a very considerable advancement in the number of telephones ordered. I think anyone can understand that provided we could talk from London to Manchester, Liverpool, and Leeds, many people would have telephones who would not otherwise have them. That is my feeling. I believe that the fusion is likely to take place, and I think it will be a very good thing for all of us if it does. It will make us much stronger in regard to our relations towards the Government. I next come to what I consider one of the most satisfactory features of the whole of the report, and that is the progress of our subsidiary companies. You see the figures before you. The Telephone Company of Austria has increased by 245 subscribers and £1,801 in income, and the Anglo-Portuguese Company (late the Edison-Gower-Bell Telephone Company) has an increase of 130 subscribers and £994 in income. I was looking back to day to see the figures in 1884 of these companies. The figures of the Telephone Company of Austria were:—626 subscribers, with an income of £4,227; and those of the Edison-Gower-Bell Company were 603 subscribers, and an income of £4,000; Those figures make a total of 1,229 subscribers, and an income of £8,227; whereas now the totals in Austria and Portugal are 3,536 subscribers, with an income of £23,255. Further than that, we have at last made those two companies absolutely money-paying concerns; in other words, the Board and friends have found money for these Companies so that they should have some working capital, which they never had before. They are now both paying us cheques for all the goods we make for them. That, to my mind, is one of the most satisfactory things I have to tell you to-day. You will notice that Mr. Buckingham has joined the Board. Mr. Buckingham was one of the earliest gentlemen I spoke to about investigating the affairs of this company, and there is, I think, no one in England I would sooner have on the Board of this Company than Mr. Buckingham. He has already been of considerable service to your Company. If any shareholder has any question to ask me which I can answer I shall be pleased to do so before putting the motion for the adoption of the report and accounts. The motion I propose is:—

"That the statement of accounts and balance-sheet and the report of the Directors and auditors, as now submitted to the meeting, be received and adopted, and that a final dividend of £2. 17s. per cent. be paid, making with the interim dividend previously paid £5. 7s per cent. for the year ended March 31st, 1888."

Sir ALEXANDER ARMSTRONG, K.C.B.: I have much pleasure in seconding that. I can add nothing to the statement of the Chairman, which I am sure the meeting will consider satisfactory,

Digitized by Google

A SHAREHOLDER: Will you answer a question before you put that? There is an item on the credit side of the balance-sheet, "Loans on security, £8,300." Will you tell me to whom that is lent, and on what kind of security?

The CHAIRMAN: It is lent to a firm of stockbrokers, and they gave us the usual Stock Exchange securities, which we can redeem from account to account.

The SHAREHOLDER: That is hardly the business of the Company.

The CHAIRMAN: You must lend your money to someone. Do you understand the difference in lending the money to a bank at 1 and 1½ per cent., and to a broker, from whom you get 2½ per cent? In the bank, too, you only have the security of the bank, but when you lend money on loan to brokers you have tangible securities.

Mr. A. E. GREEN (one of the auditors): The securities have been investigated by the auditors, and they are perfectly satisfied that you have tangible security.

The CHAIRMAN then put the motion in the usual way, and it was carried unanimously. Continuing, he said:—The next motion is the re-election of the Directors, and I propose

"*That Sir Alexander Armstrong, K.C.B., and A. H. Baker, Esq., be, and they are hereby, re-elected Directors of the Company.*"

Mr. PITT COBBETT: I think it would be in proper order if you proposed those two gentlemen separately.

The CHAIRMAN: Very well. Then I propose the re election of Sir Alexander Armstrong.

Mr. RICHARD VAN ZELLER seconded the motion, which was carried unanimously.

The CHAIRMAN: I have now to propose the re-election of Mr. A. H. Baker.

Mr. VAN ZELLER having seconded the motion.

Mr. PITT COBBETT said: It was at my instance that this business was put in this way. My object in asking that their re-election should be put separately was to have the opportunity of saying that it is not desirable, in the interests of the Company, that Mr. Baker should be reinstated in his position as a Director. Quite apart from the special conditions connected with Mr. Baker, I submit that it is not desirable that Stock Exchange gentlemen should be too largely represented on the Board of a company like this. I do not mean to say that we are not fortunate in having the present gentlemen on the Board, but I think it would be advantageous if shareholders took this opportunity of taking action in the direction I propose. I think it highly objectionable to elect any Director to whom any objection could be taken. The Company has suffered too much in days gone by to warrant its incurring further risk of the kind. I hold that it is not desirable that Mr. Baker should be re-elected, but that the nomination of a new Director be left in the hands of the Board.

Mr. WARD: I confess I am surprised at these remarks. Had they been raised at the time Mr. Baker was first proposed to the Board, I could, I think, have supported them, because I do not like as a rule Stock Exchange men to be on a Board, as there are certain objections to that course; but Mr. Baker has been on the Board for a considerable number of years, and as far as I know no objection has been made to him, or anything injurious said as to his character, or that his being on the Board is against the interests of the Company. I confess I am not prepared to hold up my hand against the re-election of a gentleman against whom the charges brought are so vague. If our friend had any charges to bring against a Director of this Company, he should, I think, state them openly, and not insinuate that there is anything against one individual. At all events, I am not prepared to take mere insinuation as a fact. I like something like truth when a charge is made against a man, showing that the charge is one which we ought to entertain.

The CHAIRMAN: I am rather astonished at the attack that has been made on Mr. Baker. So far as any gentleman saying that he does not think a member of the Stock Exchange is a good Director, I must say I cannot see it. I think that they are business men, most of them—as good men of business as any one else. That is my opinion. If the shareholders mean to say that a gentleman being on the Stock Exchange he will take advantage of the market to buy or sell the shares, then I reply that shareholders themselves are ready to take advantage of the market also. Mr. Baker is one of the gentlemen who came to the rescue of the Company for the shareholders. He has worked as hard as any man on the Board, and it seems to me a most surprising thing to say that he should not any longer be a member of the Board because certain things occurred in a club; because, after all, the Stock Exchange is a club. If anyone can tell us in what way the Company has suffered through Mr. Baker, let us have it out. Do you suppose that we have sold one single telephone less from what has happened to Mr. Baker? Do you suppose that the Telephone Company of Austria or the United Company have ordered one telephone less from us through that?

The SOLICITOR: Perhaps, gentlemen, before you deal further with this matter I should mention to you that under the 98th clause of the Articles of Association no person is eligible, unless recommended by the Directors or a retiring Director, unless his name is before the meeting by notice for seven days. It is the business of this meeting to re-elect Directors, and Mr. Baker's name is the only name before the meeting with which I can deal. Now, personally, let me say that Mr. Baker has been a most intimate personal friend of mine for 30 years. I do not think that the Stock Exchange incident has affected Mr. Baker in the least degree among those who have known him, who know him to be a man of the highest honour. I do not think it has affected him either in his business relations on the Stock Exchange, and I am sure that in the outside world he has had nothing but sympathy.

Mr. HUNTER: I wish to corroborate what the solicitor has said. If I desired to leave any business in the hands of an impartial honest man, I would leave it to Mr. Baker, who I know, as the Chairman has said, has been very instrumental in bringing the Company to the state it is now in.

Mr. BAKER: I was not unprepared for the remarks that have fallen from the gentleman in the corner (Mr. Pitt Cobbett), but I do not think that this is the place for me to vindicate myself. I can assure you I am not a man to come and ask for re-election if there was the smallest shadow of a black stain on me. I have been a member of the Stock Exchange for twenty-five years. You must bear in mind that the Stock Exchange Committee are an irresponsible body and can do as they like, and as long as you are a member of the Stock Exchange you must submit. The censure and what they chose to do with me was for a transaction entered into under the advice of my solicitor. I consider that the business transactions I ventured into were straight, business-like, and above board. I purposely chose to come here and seek re-election because when a body of gentlemen choose to pass resolutions which cannot be sustained in law, it is best to meet them face to face, to disclaim in every possible way that which has been sent round. I can assure the gentlemen who have spoken that had there been the smallest shadow of wrong against me, I should not have asked you to re-elect me. The Chairman has perfectly correctly stated that I and one of my colleagues on the right [referring to Mr. Grëwing] and the Chairman were the main instruments of bringing this Company from a state of chaos into what we may call a fairly satisfactory condition. I do not know what Mr. Pitt Cobbett's holding is, but I hold now and have held from the Company's existence about 4,000 shares. I think that many here will be perfectly satisfied to take me for what I am worth, and I shall decline to discuss my little episode any further.

The CHAIRMAN then put the motion in the usual way, and declared it carried with one dissentient.

Mr. BAKER: I am very much obliged to you for this continued mark of your approval, and I can assure you that in the future I shall endeavour to merit, as in the past, with my friends around the table that confidence which you have been good enough to bestow on me to-day.

A SHAREHOLDER: May I ask what this investment of £18,000 is—this asset of the Edison-Gower-Bell Telephone Company's shares.

The CHAIRMAN: That is one of the assets of the Company. We have 20,000 of the Preference and 15,000 of the Ordinary shares of that company.

The SHAREHOLDER: How is it that it is shown as an asset for £18,000, when there is no market for it?

The CHAIRMAN: There is no market for the shares of the Telephone Company of Austria, but they pay a dividend. Do you mean a Stock Exchange market?

The SHAREHOLDER: I do. Suppose we wanted to realise these shares, should we get £18,000 for them?

The CHAIRMAN: How can I say that? To show that we do not think this asset is as good as the shares of the Telephone Company of Austria we have written it down to-day by £2,000.

The SHAREHOLDER: Why not write it down to £5,000, as you have written it down to £18,000?

The CHAIRMAN: We must make the profits to do that. These companies' shares will gradually grow in value.

The SHAREHOLDER: If the Company were going to be wound up this asset might not realise £1,000.

The CHAIRMAN: I cannot really say what would happen in a winding up. We have saved the Company once from being wound up. Have you any Edison-Gower-Bell shares?

The SHAREHOLDER: No.

Mr. BUCKINGHAM: With reference to the question of the hon. proprietor, it is simply answered in this way. Many years ago, when this Company was formed, a large number of other companies were formed as kindred associations; and really the formation of those consisted of a mass of shares on paper. There were at that time a large number of them completely valueless. Many of the things handed over to this Board have, by judicious management—more particularly by that of the Chairman and three or four of my colleagues—become of value in the course of time, and they are daily becoming more valuable. This particular Edison-Gower-Bell asset is to my knowledge, as a new Director, the worst thing we have, but the chances are that in three or four years it may become valuable. Three or four years ago the River Plate shares were almost valueless, and now they have become valuable. As the Chairman says, there is no Stock Exchange quotation, but, nevertheless, there is a market for them. To sum up the whole, when these Directors took over this Company they took over a mass of paper belonging to certain subsidiary companies, which will, in due course, prove of some value to the Consolidated Company.

The CHAIRMAN: I have now to propose

"*That Mr. J. G. Griffiths, of the firm of Messrs. Deloitte, Dever, Griffiths and Co. be re-elected an auditor of the Company at the same remuneration as before.*"

A SHAREHOLDER: What is the remuneration?

The CHAIRMAN: Fifty guineas. That was fixed in 1884.

Mr. HENRY GREWING seconded the motion, which was carried.

Mr. GARDNER: I now propose the re-election of Mr. Green, and I should like to make an addition—that the remuneration of the auditors be the same in both cases. I understand that one of them gets fifty guineas, and the other half that amount.

The CHAIRMAN: Perfectly right. Mr. Griffiths makes a monthly audit. Mr. Green only audits the accounts. When you get a monthly audit you can see where you stand. That is the reason why Mr. Griffiths gets 50 guineas and Mr. Green 25 guineas.

It was then proposed, seconded, and carried,

"*That Mr. Arthur E. Green be re-elected an auditor of the Company, at the same remuneration as before.*"

Digitized by Google

The SECRETARY then read the notice convening the extraordinary general meeting, at which it was intimated that the following resolution would be proposed as a special resolution :—

"*To terminate the management by this Company of the business now carried on by it in Austria for the Telephone Company of Austria (Limited), and for winding up such business.*"

The CHAIRMAN : I should like to say two or three words, as this is, perhaps, slightly confusing to some of the shareholders. There is in the balance-sheet a sum standing of £127,245. 11s. 10d. That is the amount that has been spent in Austria on the telephone business there. The reason that is put in the balance-sheet "Agency account—Austria," is this, that in the year 1882, when this concession was undertaken, a company called the Telephone Company of Austria was formed. The Consolidated Company had bought the concession, and they handed it on to the Telephone Company of Austria. By Austrian law, each company working a business in Austria has to be recognised by the State. The Austrian Government declined to recognise the Telephone Company of Austria—I believe mainly on the ground that there was no capital. The Consolidated Company they accepted as a company to work that business, with the result that the Consolidated Company did the work of the Telephone Company of Austria from that date up to 1885. In 1885 we, the Board of the Consolidated Company, thought it would be better for the Austrian Company to manage its own business. It has done so ever since, and the result of that is that we have at last got a recognition for this Telephone Company of Austria by the Austrian Government. This resolution is merely to enable the old Consolidated business, which has been practically defunct for three years, to be put an end to legally. There are no figures involved in it, and no payment of expenses or anything.

The SECRETARY then read a long list of resolutions for dealing with the proposal in question.

The CHAIRMAN : You have heard this long string of resolutions read to you. You will have them all put together, I presume. I beg to propose that they be accepted.

Mr. GREWING seconded the motion, which was declared carried unanimously.

The SOLICITOR : Before you leave, perhaps I should mention that there is a slight error in the notice sent out with respect to the confirmation of this resolution. There is a little ambiguity in the Articles of Association as to special resolutions and special business, and the Secretary has given you notice, as if this were a special resolution requiring confirmation. That is not so. It is special business, that cannot be transacted at an ordinary meeting ; but the present vote is quite sufficient.

The CHAIRMAN : That concludes the business of the meeting.

Mr. WARD : Do you intend to send a report of this meeting to the shareholders, because what has just now passed is very important, and I think that all the shareholders ought to know it ? I have now to propose a vote of thanks to the Chairman and Directors for the able manner, and I think the satisfactory manner, in which they have conducted the business of the Company in the past year.

Mr. GERMAINE seconded the motion, which was carried unanimously.

The CHAIRMAN : I am very much obliged to you. I think as to the suggestion of Mr. Ward that it is desirable that we should send round a report of the meeting, and it shall be done.

The proceedings then terminated.

Institute of Medical Electricity (Limited).

The first ordinary general meeting was held at Essex Hall, Essex-street, W.C., on 7th inst. Mr. W. Lant Carpenter was voted to the chair. He said that though the meeting was called in accordance with the requirements of the statute, they had but little to report, since they had been obliged to delay the opening of an establishment in London. This was mainly owing to certain negotiations with the Royal College of Physicians (which he hoped, however, would soon be satisfactorily completed), having reference to the appointment of medical officers to the institute. The Directors had given considerable attention to the business of the institute, having held sixteen meetings since the Company was registered. Mr. F. L. Rawson, M.S.T.E. and E., had joined the Board, and it had been unanimously decided that no Directors' fees would be accepted until a dividend of six per cent. per annum should have been declared.

The meeting cordially approved the action of the Directors with reference to the Royal College of Physicians, and a resolution was passed confirming an agreement provisionally entered into by the Board, whereby the institute acquires the business of the Electrified Rooms Company of Southsea. This had been carried on for more than a year, with the warm approval and support of above forty local medical men, upon a similar principle to that adopted by this institute, viz., that no electrical treatment is administered to any patient without the concurrence, and upon the prescription, either of his own medical man or of the medical officer of the institute.

NEW COMPANIES REGISTERED.

D'HUMY CABINET BATTERY SYNDICATE (LIMITED).—This company was registered on the 4th inst., with a capital of £15,000, in £250 shares, to acquire and work the invention patented by P. R. de F. D'Humy, for domestic electric lighting, called "The D'Humy Cabinet Battery." The subscribers are :—

	Shares.
James Davidson, 8, The Avenue, Upper Norwood	1
W. W. Prole, Croyde, Devon	1
J. Johnstone, 14, Manor-place, Paddington-green	1
F. D'Humy, C.E., 2, Carlton-mansions, Clapham-rise	1
J. T. Browne, C.E., 32, Rue Baudin, Paris	1
B. H. Hertslet, Belle Vue House, Richmond	1
F. B. Lidstone, 58, Warwick-rd., South Kensington, land agent	1

Registered without special articles.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 8th, 1888, were £4,311.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 8th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,606.

RE SHACKLETON HALLETT.—The case of this bankrupt came before Mr. Registrar Hazlitt on the 9th inst. The bankrupt, a barrister, of Hare-court, Temple, has practised since 1864, and in 1882 purchased the business of William Elmore, electrical engineer, and afterwards established the Electric Company at a cost of about £10,000, which he partially borrowed. He sold the business about 1884, including certain patents, to a company named "William Elmore (Limited)," his share of the consideration being about £33,000 in shares and cash. The company is now in liquidation, and the present value of the shares uncertain. He attributes his failure chiefly to that circumstance and to losses by money lent. The unsecured liabilities are returned at £1,947. 8s. 9d. and assets *nil*. The first meeting of creditors is fixed for this day (Friday).

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 527.—Vol. XXI. FRIDAY, JUNE 22, 1888. Price 4d.

NOTES.

Very little consideration has yet been given—in this country, at any rate—to the question of electric traction on a series or constant current circuit. In America, as our readers will probably recollect, this principle has been adopted and worked out by Mr. S. H. Short. A description of the method will be found in *The Electrician* of April 29, 1887. Since that date, however, we believe that important improvements have been effected, and we have also reason to believe that the system will shortly be brought more prominently before English electricians and engineers. Under these circumstances additional interest is imparted to the paragraph in the letter of our New York correspondent in the present issue, in which he summarises the statements made in a recent controversy between Mr. Short and Mr. Sprague. The discussion would have been more instructive, perhaps, if each of these gentlemen had been less eager to depreciate the methods of his rival. It is questionable, for instance, whether Mr. Short has any right to say that Mr. Sprague would find it "practically impossible" to run 30 cars at once on the parallel system. Still less do we think that Mr. Sprague is justified in asserting that Mr. Short would require 2,450 horse-power to operate a line which he himself works with only 200 horse-power. However, these are questions upon which, as we have hinted already, we may shortly have an opportunity of forming a more definite opinion. Meanwhile, whatever other merits or demerits may be ascribed to Mr. Short's system, it is interesting to note that it possesses this highly important feature, namely, that the conductors are completely insulated throughout the greater portion of their length. In this respect it resembles the system with which Mr. Lineff has recently obtained such good results on the West Metropolitan Tramway.

In our issue of April 27 last we gave an illustration taken from a photograph of the clothes of a labourer (now in the possession of the Royal College of Surgeons) which were completely stripped from the body of a man by a flash of lightning, the man himself sustaining no personal injury. An almost identical case is now reported from America. The particulars will be found in a Note further on, taken from the *Scientific American*. That journal also gives an engraving taken from a photograph of the clothing, which has been reduced to the same condition of rags and tatters as in the earlier instance. Unfortunately, in this case the victim sustained severe injuries, from which he took some months to recover. It seems reasonable to suppose that in each of these cases the clothing had been soaked through by the rain, and thus formed a better conductor than the body; possibly there may also have been a condensing action between the adjacent layers which occasioned the disruptive effects.

Apropos of this subject we publish to-day the first of the two lectures recently delivered by Dr. Oliver Lodge before the Society of Arts, on the protection of buildings from lightning. We have previously commented upon the extreme value and interest of these lectures, and we have referred briefly to some of the remarkable experiments with which they were accompanied (*Electrician*, March 23, 1888). The text of the lectures has not hitherto been available pending their publication in the *Journal* of the Society. We may add that we have learnt with pleasure that it is probable that the lectures will eventually be republished in book form, with considerable extensions.

The fertility of Mr. Edison's inventiveness, and the zeal with which his patents were planted in every part of Europe, as well as in his native land, appear to have resulted rather disastrously in one or two instances. A test case, and one which will determine a great number of other important suits now pending, has just been decided against him in the United States Circuit Court, on the ground that his Austrian patent having expired some years ago the American patent was thereupon extinguished. About a dozen of the Edison patents relating to dynamos and incandescent lamps are affected by this decision. Some of the points are fundamental; and, according to information reaching us from the States, the manufacture of incandescent lamps is there practically thrown open to the public. But the final stage of litigation has probably not yet been reached.

The report furnished by Messrs. Alabaster, Gatehouse and Co. upon the Weymersch battery (the text of which will be found further on), justifies the belief that the depolarising fluid discovered by M. Weymersch is capable in a zinc-carbon battery of giving results of a very remarkable character. With a discharge of about 10 amperes, equal to a current density in the cell of 0·12 ampere per square inch, it was found that the E.M.F., current, internal resistance, and temperature of the cells remained practically unaltered during a period of 31 hours, after which the test was discontinued. Still more remarkable is the fact that the consumption of zinc is not more than 10 per cent. in excess of the equivalent of the electrical energy evolved. A battery capable of giving such results as these in ordinary

Digitized by Google

practice would be a very valuable addition to our resources for laboratory work, and even perhaps for electric lighting on the smallest scale and under circumstances where the frequent handling of acids is unobjectionable. We must, however, be permitted to add that we see no reason whatever to believe that the advent of this cell portends a revolution in domestic electric lighting, or that the invention possesses any extravagant value as a financial investment. We shall hope to find that the proprietors of the patent are content to rely upon the genuine merits of the invention to win the position to which it is legitimately entitled without enlisting the meretricious aid of the prospectus maker and the company monger, with abnormal ideas as to the capital required for its exploitation.

SHAREHOLDERS in the Maxim-Weston Company have so much cause for lamentation that nobody will begrudge them the amusement they tried to get out of the proceedings at its meeting last Friday. But for the assurance of the Chairman that the conduct of Mr. WATT towards Mr. SWABY was the "funniest thing in the City," and the laughter which followed the recital, we should have failed to see where the fun came in. If, however, the Mark Tapleys of the City can be jolly under such depressing circumstances, it is about the only consolation left them. The Committee of Investigation, as a last resort, propose to augment the directorate which has dwindled down to two persons, neither of whom inspires perfect confidence. When the five new directors are elected a lively time may be expected for them. At present Mr. HUGH WATT and Mr. LOUIS SWABY are the couple installed as caretakers of the Maxim-Weston property; and the master-mind in this situation being Mr. WATT, poor Mr. SWABY is alternately kicked out and restored to favour, according as he coquets with the shareholders or resumes allegiance to his better half. Meanwhile we notice that advertisements are appearing in the daily papers concerning the "*celebrated* Watt arc lamp and dynamo machine." Celebrated, in a sense, they certainly are likely to become, but it is nevertheless difficult to find anyone who can explain what they are celebrated for just at present.

THE new "Technical Instruction Bill" which has just been circulated in the House of Commons is a great improvement on the one proposed and withdrawn last year. Although excluding the teaching of any particular trade or industry, the present Bill accepts the term "manual instruction," including instruction in the use of tools and modelling in clay, wood, or other materials, instead of limiting the term technical instruction to those branches of instruction for which grants are awarded by the Science and Art Department. The proposal for putting the question to public vote has been dropped; and each board or district is to be empowered to adopt the system forthwith on the passing of the Bill; one condition, or rather restriction, being, however, that the expenditure on technical instruction as above defined shall not in any one year exceed a rate of 1d. in the pound. Perhaps the most valuable improvement is that which extends, under certain conditions, the provisions of the Bill to voluntary schools, in which, as a matter of fact, about 40 per cent. of the national education is conducted.

IN reference to the device for effecting telephonic communication between ships at anchor and the shore, which was described in our last issue, our attention has since been drawn to a communication made to a contemporary journal by Mr. F. HIGGINS in December, 1881, in which substantially the same device is described. The idea of terminating the submarine cable at a fixed buoy, and carrying thence a smaller line to the ship, is common to the two schemes. Mr. HIGGINS was, however, chiefly concerned with the permanent connection of lightships, and he proposed that when the ship had a single mast the line should be carried from a drum upon the deck up a channel in the side of the mast and over a swivel pulley at the top, passing thence to a light mast fixed upon the buoy. When the ship had more than one mast Mr. HIGGINS proposed to mount the drum upon a rail running round the ship, so that it could be shifted by hand as the vessel swung with the tide. For temporary connections it would appear from Mr. TODD'S letter that it is only found necessary to pay out some slack wire. If the wire breaks between the ship and the buoy very little mischief is done.

MR. P. DELANY having recently suggested that electric light linemen might to some extent be protected from shocks by wearing metallic wristlets and anklets connected together by a flexible wire worn under the coat sleeve, Mr. C. W. S. CRAWLEY and Mr. H. NALDER have made some measurements of the relative resistance of the two paths thus opened to the current. These will be found further on. It must be observed that the device cannot be of any value unless it should prove that the resistance from the interior of the wrists through the epidermis (that is to say, *two* thicknesses of skin) is less than that through the arms and across the chest. Mr. DELANY expressly stated that he had made no experiments upon this point, and much as we should have liked to believe that his plan would prove efficacious, it did not seem very likely that the above conditions would hold good. The result of the experiments—made, of course, with low voltages—seems to bear out the conclusion that when the current has once entered through the skin of the hand, and has to make exit by the other hand, it finds a path of lower resistance through the body than through the skin of the two wrists, even when the latter is well moistened. We are open to receive further evidence on this point; but meanwhile it seems necessary to deprecate the use of this device in actual practice with high tensions, lest it should lead to a feeling of false security, and so directly tend to increased danger. Meanwhile, the electrical industries, both in this country and in America, may well be congratulated on the remarkable brevity of the list of fatalities which they have occasioned. We very much doubt whether an equivalent amount of energy has ever been employed in any known form for an equal length of time with so few victims.

THE following paragraph appeared yesterday in all the leading daily papers:—"The Council of the British Association of Medical Electricians have appointed Mr. C. B. HARNESS, consulting medical electrician, President of the Association." The day previously an advertisement of the "Electropathic Belt" filled a whole page in the *Daily Telegraph*. Mr. HARNESS has

Digitized by Google

thus far successfully defied the efforts which have been made to awaken the public mind to a sense of the true character of his pretensions. Not even the admirable and thorough *exposé* which appeared some little while ago in the columns of our contemporary the *Electrical Review* has had any perceptible effect. It has always appeared to us, however, that this is far more a question for the medical than for the electrical profession, and while we can quite understand that, as a general rule, the medical press prefer to treat advertising quacks with silent contempt, yet, when it comes to the foundation of a regularly organised school of quackery, we venture to think that the time has arrived when the representatives of the legitimate profession should depart from their usual attitude of reserve.

A CORRESPONDENT, writing from Rangoon, sends us a cutting from the Calcutta correspondence of the *Rangoon Gazette*, from which we gather not only that the wealthier natives of India are awaking to the advantages of the electric light, but also that English electricians in India are threatened with native competition. In the case before us, however, the results were of a singularly unhappy character, and are not at all calculated to inspire confidence in native talent. The fact that the armature of a dynamo may be driven round either by a steam engine or by means of a sufficiently powerful battery has evidently impressed itself upon the native mind, but his technical education has not yet proceeded far enough to enable him to discriminate between the two cases, or when one should be used in preference to the other. Original ideas are also entertained with regard to the most suitable means of support for primary cells. However, we had better let the *Rangoon Gazette* tell its own story:—"A wealthy native gentleman, on the occasion of some marriage festivities last Tuesday, contracted with a native electrician for the illumination of his house. A large dynamo was set up, *and in place of an engine to work it, eighty Grove's cells were used.* The cells were placed upon a tucktaposh (native bedstead), *which was raised on coolies' heads, relays of coolies being employed in supporting the platform.* They were engaged for three hours, and the result was that eight of the men were seriously affected by inhaling the fumes of the nitrous oxide gas given off by the cells. Two died on Wednesday and six others are in the hospital in a more or less critical condition. Why such a dangerous and foolish method was observed is not clear." The end of the story is too tragic and pitiful to make fun of, but we should like to have been told how the lights worked, and also *why* the cells were placed on the heads of coolies. Was it for the look of the thing, or to prevent other people from smelling at them, or to let the current flow down-hill to the dynamo?

Vienna.—We understand that the Anglo-American Brush Corporation has obtained a concession for the establishment of a central lighting station in Vienna.

Omnibus Lighting.—Some fifty cars belonging to the London General Omnibus Company have been fitted by way of experiment with incandescent lamps, run off small secondary batteries.

Indian Telegraphs.—A Reuter's telegram from Bombay states that, owing to the fall in exchange, the rates for foreign telegrams to Europe will be increased by three annas a word on the 1st of July.

The Electric Lighting Act (1882) Amendment Bill.—This Bill was read a third time in the House of Commons on Thursday, June 14th, and on Monday, June 18th, the Commons' amendments were agreed to by the Lords.

Evora, Portugal.—The Lisbon papers state that a contract for lighting the town of Evora by electricity has just been sanctioned without discussion in the House of Peers. Evora is a town of 100,000 inhabitants, in the Province of Alemtejo.

Electrical Automatic Machines.—We are informed that the Nightingale Automatic Electrical Machine Company (Limited) have placed an order for 500 machines with the Vulcan Manufacturing Company, electrical engineers, Rocliffe-street, Islington, N.

Society of Telegraph-Engineers and Electricians: The President's Conversazione.—Invitations have been issued by the President of this Society and Mrs. Graves to a conversazione at the Royal Institute of Painters in Water Colours, 191, Piccadilly, on the 10th July, at 9 p.m.

Kensington.—Messrs. Verity and Sons have just completed an installation of the electric light at the Kensington Parish Church. The chancel is lighted by means of thirty 16 candle-power lamps, and there are 200 lamps of the same size in the nave. The current is supplied by "The Kensington Court Electric Lighting Company."

Berlin.—The Berliner Electricitätswerke has issued the following tariff for the supply of motive power from central stations. The tariff is based upon a utilisation of not less than 3,000 hours per annum:—

Horse-power	1.	2.	3.	5.	8.	12.
Price per hour in shillings	0·38	0·72	1·05	1·7	2·64	3·98

The Electric Light in Trains.—The example set by the London, Brighton and South Coast and the Great Northern Railway Companies in trying the electric light in a few of their trains is, we believe, to be followed by the Midland. But while it has been applied by the Great Northern and Brighton to trains which are rarely broken up, we believe the Midland will endeavour to make each coach carry its own lighting power. Some of the Great Northern Company's trains which run over the Metropolitan lines have lately been fitted with Mr. Radcliffe's arrangement of dynamos, accumulators, and gearing.

Forthcoming Exhibition at Cologne.—An Exhibition will be opened in Cologne in September in connection with the sixty-first meeting of the German Scientists and Physicians, and the preparations are already well advanced. Applications for space must be made before June 30th, and all exhibits sent in by September 1st. There will be no charge to exhibitors for space or unpacking or repacking. Any article may be sold, but must not be removed before the close of the Exhibition. We understand that over 100 firms have already announced their intention of exhibiting, including a considerable number of English.

Bath.—A private meeting of the principal citizens of Bath (who are also the largest consumers of gas in the city) was held at the Grand Pump Room Hotel, on the 15th inst., when it was decided to take at once the necessary steps for the formation of a local company to supply Bath with the electric light for private and public use. It was decided to send in a tender to the corporation for the lighting by arc lamps of a central area, at a price that would pay 5 per cent. upon the capital employed. Mr. Massingham, who was present,

Digitized by Google

promised to find £5,000 of the capital required, and also to assist the company in other ways.

Lighting of the ss. "Inanda."—Messrs. J. T. Rennie, Son and Co.'s new cargo and passenger steamship "Inanda" (London and Natal) has recently been supplied with sixty-five electric lights of 16 candle-power each. The current is supplied by a "Castle" dynamo, driven direct at 280 revolutions by a 6 horse-power (nom.) engine, supplied by Messrs. Tangye Bros., of Birmingham. The vessel is wired throughout with single lead and a "ship" return. The vessel also carries three cargo lanterns over each hatchway, with Sunbeam lamps of 200 candle-power each. The work has been carried out by Messrs. J. H. Holmes and Co., of 17, Coleman-street, and Newcastle-on-Tyne, under the superintendence of Mr. S. Crouch.

H.M. Telegraph Ship "Monarch."—Death of Captain Draper.—We regret to learn that the captain of the Government Telegraph Ship "Monarch," Mr. Draper, died of bronchitis, with which he was attacked while engaged in the recent cable-laying operations for the Post Office in the North Channel. Captain Draper expired on Sunday, the 3rd inst., at Belfast, where he had been landed for medical aid on the Friday previous. The deceased captain was 51 years of age, and had been in command of the "Monarch" since she was launched in 1883. He had previously commanded the "Dacia," and was a thoroughly experienced and careful navigator. His loss is greatly lamented by all who knew him.

Derby.—One of the principal features of the Industrial Exhibition, which has been held in Derby during the past fortnight, was the electric light exhibit of Messrs. John Davis and Son, of that town. The dynamo, which was a 4-unit "Castle" machine, was driven by a 3 horse-power "Stockport" engine, and the lamps exhibited comprised—one 2,000 candle-power "Castle" arc lamp; one 400 candle-power "Castle" arc lamp; one 400 candle-power "Sunbeam" incandescent, as well as some Edison-Swan 16 candle-power incandescents. The local gas company had offered reduced terms to the Exhibition on condition that no electric light should be allowed in the main hall, so that the lamps were confined to the entrance.

Perpignan.—The town of Perpignan will shortly be provided with a central lighting station. The town theatre is to be lit by 273 incandescent lamps of 10, 16 and 20 candle-power, at a contract price of 33fr. for each performance, which seems a remarkably low figure. Consumers having at least a three-months' agreement are charged 4 centimes per lamp-hour for a 10 candle-power lamp, 6 centimes per hour for a 16 candle-power lamp, and 7 centimes per hour for a 20 candle-power lamp. The consumption will be measured by meter if customers wish it. The renewal of the lamps has to be paid for in addition to this at the rate of 50 centimes per lamp per month, and the rent of the meters varies from 50 centimes to 3 francs 50 centimes a month, according to its size. The work is to be undertaken by M. Larny.

Edinburgh Town Council and the Electric Light.—At a meeting of the Edinburgh Town Council held on the 19th inst., the Town Clerk read a letter from the secretary of the Anglo-American Brush Electric Lighting Corporation with regard to the conditions imposed by the Town Council for permission to lay their conductors under the street for the electric lighting of Princes-street. The company thought that to enable them to go to the expense of laying conductors in the streets the contract should be for a period of not less than seven years, and representing that the rate proposed was too high, especially in view of the fact that they might not have a full demand for the first few years, and suggesting that the price should be reduced to 6d. per yard, or adjusted to a sliding scale. The matter was remitted to the Streets and Buildings Committee.

The Nordenfelt Torpedo.—A trial of the Nordenfelt electrically controlled torpedo took place on the Thames at Erith on Friday last in the presence of a number of naval and military authorities, foreign as well as English. The new torpedo measures 35ft., with a maximum diameter of 29in., its shape being that called cigar. Charged for action it weighs 6,200lb., its equipment consisting of 300lb. of explosive, which can be increased to 500lb., 120 electric storage cells, a motor weighing 780lb., and 3,000 yards of cable, which is played out as the boat travels. It is driven by a screw propeller and steered by a balanced rudder, the speed being 14½ knots. This weapon is intended for harbour or coast defence, and requires no prepared base to operate from, a small boat towing it to any required position, from which it can be electrically controlled and manœuvred in any direction and at any range within the limits of its cable, and exploded when its object is reached. The trial on Friday was entirely satisfactory. The electrical details have not been fully disclosed.

Electric Launches on the Thames.—We mentioned some time since that Messrs. Immisch and Co. proposed to establish a series of stations on the River Thames, by which current might be obtained for charging accumulators on electric launches. The first of these stations has now been completed on board a hulk which is at present moored in the river a little below Kew. On Saturday last Messrs. Immisch and Co. invited a party of friends to visit this station, and to make a trial trip in an electric launch, which has just been completed for service at this station. Previous to starting up the river the ceremony of christening the launch was performed by Mrs. Immisch, and the boat received the name of "Malden." A landing was effected at Eel Pie Island, where the company were entertained at dinner, and in the evening the party returned to the charging station, after an extremely successful and a very pleasant trip. We shall shortly give further technical details of the arrangements adopted.

The Copper Syndicate.—An American paper says that the French syndicate is not satisfied with binding the leading producers of copper throughout the world in a three years' contract not to sell under a certain figure, supposed to be 13c., but has now made contracts with copper consumers. In this way it hopes to protect both parties with a cast-iron rate which is remunerative to all parties. Referring to this last operation of the French syndicate, a contemporary says:—"The contract is for between £30,000,000 and £40,000,000 at 16·50c. The terms were originally for six months, but it is believed it has since been changed to four months; it is certainly not less than the latter. The syndicate agrees not to allow the price to decline below 16·50c. The consumers, on their part, can purchase what copper they want for consumption, but cannot resell upon the market, and as all ingots, cakes and bars are stamped, they can easily be traced, and the party found reselling can be held liable under the contract."

The Committee of the Royal Meteorological Society on Thunderstorms.—At a meeting of this Society, held on Wednesday evening, the 20th instant, the first report of the thunderstorm committee was read. This report deals with the photographs of lightning flashes, some 60 in number, which have been received by the Society. From the evidence now obtained it appears that lightning assumes various typical forms, under conditions which are at present unknown. The committee consider that the lightning flashes may be arranged

Digitized by Google

under the following types:—1. Stream. 2. Sinuous. 3. Ramified. 4. Meandering. 5. Beaded or chapletted. 6. Ribbon lightning. In one of the photographs there is a *dark* flash of the same character as the bright flashes, but the committee defer offering any explanation of the same until they get further examples of dark flashes. As the thunderstorm season is now coming on, the committee propose to publish their report at once, along with some reproductions of the photographs by the autotype process, in order that observers may be prepared to notice the various forms of lightning.

Incandescent Lamp Experiments.—At a recent meeting of the Société Française de Physique, M. Mascart described some interesting experiments which he had carried out with a view of determining how far incandescent lamps might be a source of danger when in the immediate vicinity of inflammable materials. Some 32 candle-power incandescent lamps were tightly enveloped in cloth, others in wadding, with the gummed surface removed, and others, again, were placed in the folds of some old stage scenery; in no case was there any charring or undue heating. An extra thick cotton hood placed over a 32 candle-power lamp became charred wherever it was in contact with the globe after ten minutes had elapsed. A 32 candle-power lamp which was surrounded by a black silk hood and then by a black velvet one, set the latter burning gradually in six minutes. In another experiment two lamps were enveloped respectively in black and white wadding, from which the gummed surface had *not* been removed, and in two minutes charring commenced, both lamps burst, and the wrappings were set alight. Finally a 300 candle-power lamp was laid against some old scenery; in a minute and a-half the scenery began to char where the globe touched it, and slowly burnt without flame.

Acid or Resin for Wire Joints.—Our Boston contemporary *Modern Light and Heat* contains the following letter on the use of acid as a flux in soldering electric light wires. The writer is an inspector of the Boston Fire Underwriters' Union:—"I am often asked why I prefer acid to resin to solder joints in electric light wires, and, with your kind permission, should like to answer through your valuable medium. I do not prefer it, but think that we get better results from acid than resin. It is safe to say that only one out of ten knows how to make a good joint with resin, or if they do know they will not take the trouble. You, of course, know, as do many others, that the secret of joints made from resin is a perfectly clean surface. This, of course, requires some care, while with acid, if the wire has any oil or grease, or any of the insulation which the linemen have failed to scrape off, the acid will do the work which the workmen (by name, but not by nature) have failed to do. I have learned from experience that the wires eaten off by acid are so few that the danger of fire from such cases is less than those from poor joints with resin. I hope that some time in the future we shall have men that we can depend on to make joints with resin."

Catalogue of the Consolidated Telephone Construction and Maintenance Company.—The illustrated catalogue of the Consolidated Telephone Construction and Maintenance Company affords a tolerably complete exhibition of the telephonic appliances in use in this country. There was a period when the Patent Offices in this and other countries were reaping large revenues from the unceasing "invention" of "improvements" in telephonic apparatus, but owing, chiefly no doubt to the firm grip with which the holders of the Bell and Edison patents have maintained their hold upon the fundamental principles of telephony, the appliances at present in the market bear no traces of outside influence, the only surviving exceptions being those earliest in the field, such as Gower, Blake, and Hunnings. In view of the fact that the instruments made by the Consolidated Company are unquestionably efficient, to a degree approaching perfection, the fact is an instructive one. Several forms of switch-boards are illustrated in this catalogue which are well adapted for exchanges of moderate size, and are much cheaper than the "Multiple" board, though for installations of 1,000 subscribers and upwards nothing else has yet proved equal to the "Multiple." The Consolidated Company also make a good many specialities in the way of divers' and mining telephones, &c.

The Westinghouse Company and a New Incandescent Lamp.—The following statement appears in the *American Engineer*: M. de Routhamsky, secretary of the Russian Legation to the United States, was recently in Pittsburg, and spent several hours in consultation with Mr. George Westinghouse, jun., and other members of the Allegheny County Electric Light Company. In explanation of his errand he said: "I came here on behalf of a fellow-countryman, for whom I have just concluded an important contract with Mr. Westinghouse relating to incandescent lamps. My countryman has made a discovery which will probably have a greater influence on electric lighting than any of previous years. I am not at liberty to give the details of my transaction here to-day, but I will say this much, that the discovery relates to a filament to be used in incandescent lamps that is capable of standing so high a temperature that from two to four times as much light can be secured from a given expenditure of power as has been claimed by the Westinghouse and Edison Companies. The lamps which are supplied with those filaments will give more light for the horse-power than two arc lamps, and I think it is reasonable to look forward to the gradual displacement of the arc light. I think the effect on electric lighting will be very marked, as it will at once double the capacity of existing plants and will save 10 per cent. in fuel, which has all along been about one-third of the cost of operating."

Lighting of the Langham Hotel.—This magnificent building in Portland-place, which forms one of the finest hotels in Europe, has just been lighted throughout by electric light. Towards the end of last year the directors determined upon carrying out this important work, and requested some of the leading firms to send in tenders and give a detailed scheme as to how the work would be carried out, together with samples of all electrical apparatus proposed to be used, as well as designs of electroliers, pendants, brackets, or other devices proposed for lighting the different rooms throughout the building. It was eventually resolved to place the work in the hands of Messrs. B. Verity and Sons, of King-street, Covent Garden. The coffee room, which is the finest room in the building, is lighted by four rows of brass pendants, with large crackled glass shades, the inner row having three lamps, and the outer row two lamps each, making in all eighty lamps of sixteen candle-power. Next in importance comes the drawing or general sitting room, which is lighted by four handsome ormolu chandeliers in the style of Louis Seize, with crackled glass shades, the tops of the chandeliers having a star of gas jets for use in the event of a failure in the electric light. The same system is carried out in the ladies' room, gentlemen's writing room, smoking and billiard rooms, &c. The bed rooms are lighted throughout with one or more lamps according to size, as well as the private sitting rooms, these being lighted with electroliers of a neat and pretty design. In the whole of these rooms and also in the bed rooms the switches for controlling the light are placed by the

Digitized by Google

side of the doors and have printed instructions over them as to their use in English, German, and French. The corridors are provided with pierced brass canopies and glass shades, suspended by crimson silk cords; also all the lavatories, &c., are lighted in a similar manner, together with all the kitchens, serving rooms, pantries, &c. The current is taken from the Grosvenor Gallery central station in Bond-street. The transformers, of which there are eight, are placed in a specially constructed building in the yard at the rear of the hotel, and the secondary cables are run from thence to the different floors. Altogether there are at the present time 1,400 lights; the whole of the cables and wires (of which there are many miles) have been manufactured especially for the purpose, as have also the different switches, safety fuses, electroliers, pendants, &c. The whole of the work has been completed in four months, and, considering the substantial character of the work, it constitutes one of the quickest jobs on record. The works were carried out under the direction of Mr. J. Elwin Coles, the manager, and also Mr. J. G. S. Cunnington, the electrical engineer, of B. Verity and Sons.

A Remarkable Escape from Lightning.—The *Scientific American* contains a letter from Mr. John De Motte, of De Pauw University, which furnishes the second instance on record of a man having his clothes destroyed by lightning without fatal results to himself:—"The narrowest escape from death by lightning of which I have ever heard came to my knowledge while lecturing a few weeks ago at the Florida Chautauqua. The drug store, which is used as a post-office by the good people of De Funiak, stands between the railroad station and their beautiful little lake. At the time to which I refer it was 'protected' by a common-sized twisted copper-band lightning rod, with iron core, fastened to the house by glass insulators in the old-fashioned way. Several other houses in the town were 'rodded' in the same way; but after this one was so badly shattered they were torn off by their owners, 'to lessen their chances of getting struck, you know,' they explained. About a hundred feet back of the post-office stood two fine specimens of the tall pines which grow so abundantly in that region. On the afternoon of the 18th of last August, at about one o'clock, a number of boys and men had collected under the post-office porch, thinking, on account of the lightning rod, that they would be safe from the lightning, which was playing rather freely from an only partially cloud-covered sky. Among them was John Chisholm, a merchant of De Funiak, who was sitting about half way between the corner post of the porch and the nearest window. The lightning struck the two high pines, and, after shattering their tops, leaped to the rod, completely melting its points, and then, running along the comb of the roof to the gable and down a corner, demolished that portion of the building. Mr. Chisholm's only recollection of the stroke is a sensation like that of a heavy blast of hot air striking him between the shoulders. He was thrown forward upon his face and taken up for dead. His shoes and trousers were left looking very much as if they had been attacked by an army of hungry rats. How a man could have his clothes chewed off from him by lightning in that style and still live is a mystery. His shirt was torn entirely in two. His body was badly blistered, especially from the knees down. Becoming conscious, he experienced a terrible feeling of suffocation and 'heartache, as though it would burst.' He remained helpless for four months, suffering terribly from an aching in the bones and stinging sensation, 'as though a thousand needles were being stuck all over my body.' Now, after a lapse of over nine months, Mr. Chisholm has gradually recovered the use of his limbs, only suffering from an occasional violent involuntary jerk in the back. Several others sitting near were, of course, more or less shaken up. Dr. Allred caught a part of Mr. Chisholm's charge in his foot, and went on crutches for some days."

The Melbourne Centennial International Exhibition—The arrangements for the lighting of the building of this Exhibition with electricity are well under way. The Australasian Electric Light, Power, and Storage Company hold the contract for the exhibition building and the main annexes, and they are following closely on the heels of the builders and the decorators. The whole of the leads for the arc lights have been fixed, and are ready for the lamps. To give some idea of the magnitude of this part of the work, it may be stated that about 27 miles of leads have been used. To the casual observer, however, very little of them can be seen, care having been taken to keep them out of sight as much as possible, and to avoid ugly festooning of the wires. The installation is being carried out under the personal supervision of Mr. R. E. Fletcher, the company's electrical engineer, who also carried out the lighting of the Adelaide Jubilee International Exhibition last year. The Brush arc and Victoria incandescent dynamos and lamps are used throughout. The lighting of the Melbourne Exhibition will exceed anything of the kind that has hitherto been attempted in our own country. The contract is for 825 10-ampere Brush arc lamps and 2,000 16 candle-power incandescent lamps, with the necessary dynamo machines, conductors, fittings, &c. There will be 37 Brush dynamos, each capable of supplying current to 23 Brush arc lamps, and 7 Brush-Victoria dynamos, each supplying current to 350 Swan incandescent lamps. Power for driving the machines will be supplied by six horizontal engines, coupled in pairs, each pair capable of giving about 500 horse-power. Steam for these engines will be supplied from 12 boilers. Every precaution is being taken against a failure of the light. The countershaft is divided into several sections, and any of the dynamos or engines can be stopped without interference with the others. The arc lamps will be arranged so that no two lamps supplied with current from the same machine come together. Half the lights could be extinguished without causing any serious inconvenience, as the buildings would still be better illuminated than with gas. In the main building, the dome, naves, and transepts will be lighted with Brush arc lamps, and the picture galleries, wine cellars, the space under the galleries in the main hall, the aquarium, retiring rooms, offices, &c., will be lighted with incandescent lamps. In the annexes the Brush arc lamp will also be employed. The total area to be lighted is as follows:—Arc lighting, 943,135 square feet of floor space, or about 1,144ft. per lamp; incandescent lighting, 119,000 square feet floor space, about 58 square feet per lamp. The seven incandescent dynamos are compound-wound and will be joined up in parallel. This makes practically one machine of the seven, the work being distributed evenly amongst them all, but with the advantage that one or two of the machines could be disconnected from the circuit in a few seconds if necessary. There is every prospect of the electric light being ready five or six weeks before the opening of the Exhibition, provided the engines and boilers, which are being made by various firms in Melbourne, can be supplied in time, of which there seems to be every probability. Messrs. Ganz and Co. are to light up the reception rooms with about 290 incandescent lamps of 16 candle-power, and the armament court and part of the machinery annexe, covering about 30,000 square feet of space, with 30 arc lamps, the whole of which will be worked by Zipernowski-Déri transformers. Messrs. W. H. Masters and Co. have made an offer to light the western machinery annexe with 78 arc lamps of 2,000 candle-power, but the contract has not been let.

UNIPOLAR INDUCTION.—III.

BY G. W. DE TUNZELMANN, B.SC.

(Continued from page 171.)

The first to employ an electro-magnet to exhibit the phenonema of unipolar induction was E. Hoppe, whose apparatus is described in a Paper published by him in Vol. XXVIII. of Wiedemann's *Annalen*, 1886.

In a Paper published in the *Sitzungsberichte der Wiener Akademie* in July of the same year, Exner and Czermak described some experiments made by them in which they also used an electro-magnet.

Their apparatus consisted of a cylindrical bar of soft iron, one half of which was surrounded by a magnetising helix, and the other by a metallic jacket. When the ends of the jacket were connected with a galvanometer, the results obtained were similar to those obtained with Fessel's apparatus, with which it was practically identical. These two physicists then investigated the current in the jacket without using a fixed conductor. As it was impossible to use a galvanometer for this purpose, they devised the plan of connecting the ends of the jacket with the axis of rotation through a silver voltameter placed inside the jacket, and rotating with it. The induction current produced in the jacket caused polarisation in the voltameter, and this polarisation was tested without stopping the rotation by disconnecting the terminals of the voltameter from the ends of the jacket and placing them in connection with the terminals of a galvanometer, when the polarisation produced a momentary deflection of considerable amount in the galvanometer, and a smaller permanent deflection.

In one experiment the electro-magnet was rotated at a constant speed, while the jacket remained at rest, and at the end of a quarter of a minute the polarisation was tested and gave a swing of 145 scale divisions. The jacket was then made to rotate at the same speed and for the same time, when a swing of 143 scale divisions was obtained, so that the two results were as nearly identical as could possibly be expected. When the magnet and the jacket were rotated together, the swing obtained was only 0·8 of a scale division, so that there was practically no effect.

The ends of the jacket were then connected directly through the voltameter by means of a wire, and it was found that no current was produced when the jacket and the wire rotated together about the magnet, or when the magnet was rotated while the jacket and wire remained at rest.

All the experiments which we have described will be found to be very simply explained by the law of electro-magnetic induction, discovered by Faraday, that *the total E.M.F. induced in a closed circuit moving relatively to a magnetic field is equal to the rate of decrease in the number of lines of force which pass through the circuit*, provided we make the assumption that the system of lines of force, or the magnetic field of a magnet, rotates with it.

In our next article we shall consider the physical meaning of this assumption.

In order to understand clearly the application of this law to the different experiments which have been described, it may be well to recall some properties of magnetic lines of force which are summed up in the law of induction just stated.

A line of force is a vector quantity—that is to say, if it is turned end for end, its action is reversed. The positive direction is usually taken to be the direction in which a free north pole would tend to move along a line of force.

As a line of force passes through a closed circuit from the outside to the inside, or *vice versâ*, it sets up an E.M.F. along the circuit.

If the line of force passes from the inside to the outside of the circuit the E.M.F. produced is such as to cause a current passing round the circuit in the direction of the hands of a watch placed so that the positive direction of the line of force passes through the watch from the face to the back.

It follows from the vector nature of the lines of force that if a positive and a negative line pass through the circuit in the same direction, the currents produced will be in opposite directions, so that the total current will be zero. When, therefore, we speak of lines of force crossing the circuit continuously in the some direction, we mean that the lines are all of the same sign, and that they all pass either from the inside to the outside of the circuit, or *vice versa*.

It is clear that when a magnet having its axis fixed is made to revolve relatively to a fixed external circuit, no current can be produced, for the number of lines of force which pass into the circuit during any given time must be equal to the number which pass out of it during the same time. In other words, every line of force will cut the circuit twice in opposite directions.

When the terminals of a fixed circuit are connected with the two poles of a magnet revolving about its axis, it is also clear that no current will be produced, because for every positive line of force, coming from the north pole of the magnet, which crosses the circuit in a given direction, a negative line of force coming from the south pole of the magnet will cross it in the same direction.

In the experiment of Fig. 1 the disc C is continuously cutting the lines of force in the same direction, and no lines of force are cut in the opposite direction, so an E.M.F. will be produced acting along the radius of the disc.

In the experiments Figs. 2 to 8 the central portion of the magnet itself takes the place of the disc, and the reason that the strongest current is produced when contact is made near the centre of the magnet is that in that case a larger number of lines of force cut the circuit as the magnet revolves relatively to it.

In the experiments Figs. 10 and 11 the number of lines of force crossing the circuit in one direction is greater than the number crossing it in the other, and therefore a current is produced.

With respect to the experiments in which a jacket is used, it will be convenient to summarise the results already obtained.

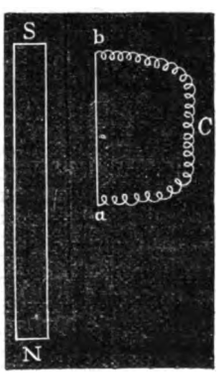

FIG. 12.

Let N S (Fig. 12) be a cylindrical magnet, which may be either a permanent steel magnet or an electro-magnet. Let *a b* be the section in the plane of the paper of a metallic jacket surrounding, and concentric with, the axis of the magnet. Let *a c b* be a metallic wire with its ends in contact with the upper and lower edges of the jacket respectively. The results obtained may then all be included under one of the following heads :—

1. If the jacket only rotates a current is set up round *a c b*, which is reversed in direction when the direction of rotation is reversed.

The current is produced by the lines of force crossing the jacket continuously in the same direction, while no lines of force cross the rest of the circuit.

2. If the magnet and the jacket rotate together a current is obtained of the same strength and in the same direction as before, due to the lines of force crossing the wire *a c b*, while the jacket remains, relatively to them, at rest.

3. If the magnet rotates while the jacket and wire remain at rest there will be no current, for as the lines of force cross both portions of the circuit in the same direction there is neither increase nor decrease in the total number passing through the circuit, and therefore no E.M.F. round the circuit.

Digitized by Google

4. If the magnet remains at rest while the jacket and the wire rotate together there will be no current, the relative motions being the same as in case 3.

5. If the magnet and the wire rotate with the same angular velocity while the jacket remains at rest a current will be produced by the lines of force crossing the jacket.

6. If the wire *a b c* is removed and the edges of the jacket are joined to the axis, then if the magnet is made to rotate while the jacket is at rest, or if the jacket is made to rotate while the magnet remains at rest, a current will be produced by the lines of force crossing the jacket continuously in the same direction.

(To be continued.)

THE PROTECTION OF BUILDINGS FROM LIGHTNING.*

BY DR. OLIVER LODGE.

One hundred and fifty years ago the nature of lightning was unknown. Several persons surmised that it had some connection with the phenomena excited in a piece of glass tube when rubbing it, phenomena which were called electric; but no proof of the connection was attempted. The proof that lightning was, in fact, nothing but a large electric spark was given, as you know, in 1751, by that marvellously comprehensive and commonsense genius, the Philadelphia printer, Benjamin Franklin.

This great man, a statesman of the first magnitude, might have made one of the first experimental philosophers, had he lived in quieter times instead of having to take a prominent part in the Declaration of Independence and in the great American War. A space of some twelve years limits his active devotion to electrical matters, but in that time he acquired a masterly grip of the subject, expressing himself very accurately and precisely concerning electrical theory, his statement of which is far superior to a great deal that has quite lately passed current in text-books; indeed, it is only now becoming capable of improvement through the labour and the inspiration of some of the still greater giants of our own day.

From the time that Franklin flew his kite at Philadelphia and ascertained beyond cavil the true nature of lightning, from that time to the present the protection of buildings and ships from its destructive agency has been mainly a matter of detail and application of the laws of eletricity so far as they were known.

For a long time the erection of lightning conductors was opposed by the religious world as heretical and impious. But, first in some Protestant provinces in Germany, and later in France and England, the use of the heretical rods gradually extended. The extension of their use in England and their application to ships were greatly aided by the labours of their enthusiastic worker, Sir W. Snow Harris. Their extension in our South African colonies, where violent thunderstorms are frequent, is largely due to the influence of the late Dr. Mann, in whose honour this course of lectures has been established. Anyone who has read or heard Dr. Mann's contributions to the *Journal* of the Society of Arts,† must have been struck, not only with his keen interest and enthusiasm, but also with his grasp of fundamental principles, his open-minded receptive attitude to new controvertible views, and the thoroughly practical and business-like way in which he handled the subject.

Concerning the origin of atmospheric electricity I have not much to say. It seems to me probably due to friction, like Armstrong's hydro-electric machine. Faraday showed that the exciting cause in that apparatus of Armstrong's was the friction of water spray driven by steam over the solid surface of the jet; so also I picture winds in the atmosphere driving the spray of mist against rock and ice surfaces, and so gradually producing a certain difference of potential between the upper layers of the atmosphere and the surface of the earth.

I have spoken as if I thought the friction had to be between mist globules and solid matter. It seems doubtful whether friction against air will suffice to render water electric. If it is efficient, then it is well to notice that, though there is no finite slip between bodies and the common air through which they move, yet this does not apply to rarefied air. The viscosity of rare air is as great as that of dense, but the slip of solids through it is another matter. In rare air there is an actual slip at the surface, and accordingly the *apparent* viscosity of rare air, as observed by the settling of dust or the falling of a feather in a vacuum, is less than in air at common pressure. It may be, therefore, that the finite slip of mist or dust-particle through the upper layers of the atmosphere is one effective cause of atmospheric electrification, and after a spell of dry weather there is liable to be an accumulation of electricity, because it has had no recent opportunity of escape.

In the polar regions electrical discharges are mainly silent, or brush-like, giving the fantastic forms of aurora. But in our latitude these silent discharges in the upper semi-conducting rarefied layers of atmosphere are seldom visible. We see the effect in another form. The electrification gets occasionally conducted down by clouds into the lower and denser layers of atmosphere. By the aggregation of small globules into great ones the potential is enormously raised, until in the lower atmosphere they flash either into each other or into the earth, and the strain is partially relieved.

It is important to note that clouds appear to play only a secondary part in the phenomena. The upper regions of atmosphere are at a different potential from the earth—cloud or no cloud. Clouds are able to conduct it down towards the earth, and thick dense clouds are therefore the usual prelude to a thunderstorm.

The way in which the coalescence of small charged globules into larger globules is competent to raise their potential enormously is well understood, and I need not dwell upon it;* but the converse operation, or the tendency to coalescence of globules produced by feeble electrical charges in their neighbourhood, is not so well known, and I proceed to show the very simple experiment described by Lord Rayleigh, with a water-jet and sealing-wax.

A vertical jet about one-twentieth of an inch in diameter and three or four feet high does best, but almost any fairly vertical jet of clean water will serve. The drops fall as a scattered shower like fine rain until a stick of excited sealing-wax is held a yard or two away; they then instantly collect into large globules and fall as a thunder shower.

We have now to think of ourselves as living always between the coatings of a large condenser or Leyden jar, the upper coating the sky, the under coating the earth; the common air is the dielectric between. Ordinarily the sparking distance is far too great. Every now and then portions of the upper coating protrude down as clouds, and we are then liable to a disruptive discharge. Some square miles of cloud and some square miles of land are the two coatings, and the interval of separation need not be extremely great. If the cloud and the earth were perfect conductors, all this great area would be relieved in a single flash of awful size; but, fortunately, the conduction of cloud is a slow process, and it usually takes a good many flashes from different parts to remove its charge.

The total maximum energy of a given area of cloud at a given height from the earth is easily estimated, for it is well known that as soon as the electric tension of air reaches the limit of about half a gramme wt. per square centimetre, disruption occurs. Supposing it all equally on the verge of giving way, the energy of the dielectric per cubic centimetre is therefore $\frac{981}{2}$ ergs, and per cubic mile is $\frac{4{,}110 \times 10^2}{2 \times 3 \times 10^7}$ foot-tons = 70,000,000 foot-tons.

Given, then, the whole area of cloud facing the earth, and its height when on the point of discharging at every point, and you have the number of cubic miles of strained dielectric, and an approximation to the energy of the storm, at the rate of 70,000,000 foot-tons per cubic mile.

The potential needed to give a spark a mile long is so enormous† that the quantity of electricity required to give this energy need not be very great; $2{,}176 \times 10^8$ electrostatic units of quantity per square mile would give a bursting tension. Now, $2{\cdot}176 \times 10^{11}$ electrostatic units is just about 70 coulombs, or not enough to decompose one-hundredth of a gramme (1-7th of a grain) of water.† Faraday stated this, but it is often disbelieved.

As to the cause of the curious V-shaped troughs or depressions and horizontal whirls that are often found associated with thunderstorms, I have no suggestion to offer; but on those heads I may refer to Mr. Abercromby's recent little book on the "Weather" (Int. Sci. Series, 1887).

Thinking now of a cloud and of the earth under it as forming the two coats of a Leyden jar, in the dielectrics of which houses and people exist, we have now to consider what determines a discharge, and what happens when the discharge occurs. The maximum tension which air can stand is $\frac{1}{2}$ gramme weight per square centimetre. At whatever point the electric tension rises to this value smash goes the air. The breakage need not amount to a flash, it must give way along a great length to cause a flash; if the break is only local nothing more than a brush or fizz need be seen. But when a flash does occur it must be the weakest spot that gives way first— the place of maximum tension—and this is commonly on the smallest knob or surface which rears itself into the space between the dielectrics.

If there be a number of small knobs or points the glows and

† The difference of potential for a spark a mile long, between flat plates, is roughly 16×10^7 electrostatic units.

Digitized by Google

brushes become so numerous that the tension is greatly relieved, and the whole of a moderate thunder cloud might be discharged in this way without the least violence. This is by far the best way of protecting anything from lightning; do not let the lightning flash occur if you can possibly avoid it. But one cannot always prevent it, even by a myriad of points. A good deal more might be done in this direction than is done, but still, sometimes a cloud will descend so quickly, or it will have such a tremendous store of energy to get rid of, that no points are sufficiently rapid for the work, and crash it all comes at once. One specially noteworthy case when points are no protection occurs when one cloud sparks into another, and thence to the ground; or, in general, whenever electric strain is thrown quite suddenly upon a layer of air. (See Lecture II. for details.)

When a flash occurs a considerable area is relieved of strain, and the rush of electricity along the cloud and along the ground towards the line of flash sets up a state of things very encouraging to another or secondary flash or flashes practically simultaneous with the first.

One consequence of this is known as the back stroke or return stroke. It was studied by Lord Mahon, and depicted in his work, "Principles of Electricity," published in 1780. Professor Tyndall has made it extremely well known, so that a reference to it is made in almost every elementary science school in the country.

But the popular account of the matter is, I believe, very inadequate. It says the man's electrical condition is disturbed by the inductive action of the cloud, and that on the cloud being discharged the man's original condition is restored; the passage of the induced charge from his hat to the ground being enough to kill him.

Now the shock that a man could get that way is but feeble; it is only twice what he would get if completely isolated and exposed to inductive action. The amount of charge stored up in a man's hat is not great; the electric tension is more likely to pull his hat off than its release is likely to do him any damage.

I do not deny the existence of this static return shock, but I assert it to be impotently feeble. One can feel all there is to feel by holding a hat near an electric machine till nearly bursting tension, and then discharging the machine. There is no special object in waiting for a thunderstorm.

There is more in the "return stroke" than a mere recovery from statical disturbance of equilibrium. It is a matter to which I must return at some length next week.

Now proceed to the kind of damage done when a building is struck, and to the customary and orthodox modes of protecting them from the effects of the flash when it does occur, as well as if possible of warding off the flash altogether by silent discharge. The two main destructive aspects of a lightning flash are—(1) its disruptive or expanding or exploding violence; (2) its heat.

The heating effect is more to be dreaded when the flash is slow and much resisted; the bursting effect when conducted well except at a few places. A noteworthy though obvious thing is, that the energy of the discharge must be got rid of somehow. The question is, how best to distribute it. It is no use trying to hocus-pocus the energy out of existence by saying you will conduct the charge to earth quite easily and quietly.

The disruptive effect is well shown by the effect of lightning on trees. It is as if every cell were burst by the expansion in the path of the discharge. The effect on conductors is, however, just as marked. Here are five specimens of wires deflagrated on glass by a Leyden jar discharge—gold, silver, copper, iron, and platinum; each has its characteristic trace, by which it can easily be recognised.

[A number of pictures of damage done to buildings and ships by lightning were here thrown upon the screen. They are mostly contained either in Mr. Anderson's work on "Lightning Conductors," or in Mr. Tomlinson's on the "Thunderstorm," or in both.]

St. George's, Leicester, is a curious case, for the rod of the vane conducted the flash half-way down the spire, when it blew a ring of stones out, and so dropped the top half of the spire neatly inside the bottom half, making a tremendous smash, carrying away all the floors of the tower, and beating in the foundation-arch.

Ships may have a mast utterly destroyed and split to pieces—thick iron hoops binding the mast being rent asunder and flung about by the force of the expansion; or the heat of the flash may ignite the sails or some other combustible matter.

Now take a few examples of buildings or ships more or less protected by conductors. Some of these examples are very instructive as calling attention to the vagaries and unexpected behaviour of powerful flashes. It is these vagaries which I consider have been hitherto unexplained, and it is precisely these to which I wish to direct your special attention.

I shall hope to show next week how closely and completely they can be illustrated by laboratory experiments, and I believe that it is to a neglect and misunderstanding of these phenomena that so many of the partial failures of conductors have been due.

For that conductors often fail is undeniable. It is customary to say that they are not properly made, or that there was a faulty joint, or that there was a bad earth. A bad earth is the favourite excuse. A good earth is a good thing undoubtedly, and one cannot well have too much of it; but for a flash to leave a fine thick copper conductor on a tall chimney while still high up, and begin knocking holes in the brickwork in order to make use of the soot or the smoke or some bolts or other miserable conductors of that sort, because it is not satisfied with the moderate allowance of earth provided for it at the bottom, is evidence either of simple perverseness or else of something more deep-seated and not yet properly called attention to.

If the earth is bad, the flash can show its displeasure when it gets there by tossing it about and boring holes into it, and breaking water and gas mains; but at least it might leave the top and middle of the chimney alone—it might wait till it got to the badly-conducting place before doing the damage. Yet it is notorious that on high chimneys a flash often refuses to follow a thoroughly good conductor more than a quarter or half-way down, but takes every opportunity of jumping out of it and doing damage.* Why is this? Well, that is the main question I shall attempt to answer in this course.

It may be said that the effect of the bad earth is to make the whole path so highly resisting that the discharge necessarily declines to take it. Well, if that were so, it need not have come into the conductor at all. It is supposed with one breath to strike the conductor because it affords an easy path to earth, and with the next it is said to leave the conductor, because after all it finds it a bad one.

Besides it need not be so very particular about a little resistance; it has already come through, say, half a mile of clear air, it might manage a few feet of dry soil. It strikes violently through the air, enters the conductor, and begins to go quietly. Why does it not continue to go quietly till it gets to the bottom of the good conductor, and *then* begin displaying its vigour by boring holes below, as it has done above? Why should one end have to be so persistently cockered up? Why not insist upon having not only a good "earth," but also a good "sky"?

Let me repeat a good earth is a good thing, and it is not possible to have too much of it, except on the score of expense, but even if it were so good an earth that it might be almost called a heaven, it would not stop the tendency to side flash. One would be still liable to spittings out from conductors, especially from tall stout ones, as I shall hope to clearly show next time. However bad an earth may be, it can hardly be worse than one afforded by soot, and bricks, and yards of air.

My position at present is that an earth is desirable to prevent damage to pipes, foundations, and other things buried therein. But that, *so far as getting rid of the flash is concerned*, it ought to suffice if the conductor was cut off level with, or even a foot or two above, the ground. It would knock things about in jumping the rest of the way, but it should not be expected to leave the conductor until it gets to the break, any more than it should be expected to take the conductor half way down instead of at the top. It is true it sometimes *does* partially take the conductor at the middle, just as it sometimes partially leaves it at the middle, but I say that it is not to be expected to do either of these things on ordinarily accepted principles. There are some differences between the behaviour of positive and negative electricity, but none of such extent as will explain the extraordinary difference between the two or three points pointing skywards and the extensive roots advocated at the other end.

Take these examples now. A house where the lightning, having struck the conductor, flashes off from it in two places to get to a roof gutter and a distant water-butt. Here is a ship where the lightning is striking in two places at once, the top of the mast and the yardarm. In the next it is striking at the top of the conductor, and also at a point on deck, and at two places on land as well. This is a most instructive example. I have little doubt that the three are echoes or reverberations of the main flash, and excited by it; not excited by induction as in a coil, still less by mere static return, but by a surging or momentum of electricity, of which I have more to say. The next diagram shows the ship "Conway" capitally protected, except as to its flagstaff. The water was seen to be luminous in conducting away this flash from the sides of the ship. Here is the arrangement by Snow Harris of conductors able to accomplish this protection—simple and effective. A ship is an easy thing to protect, provided you realise that every mast and every spar is liable to be struck. If you protect the masts you may chance the spars if you like; but you are not to think of areas of protection; all such ideas are perfectly illusory.

[Figures of certain houses with elaborate conductors were shown.]

Nothing projecting upwards is left unspiked, and the earths are thorough. These appear to be examples of excellent, though certainly expensive, protection.

If these house were powder magazines we should have to be more

* For an example of the entire failure of a brass rod, 1in. in diameter, *see* Anderson's book, p. 137. For cases of capricious leaving of a conductor for such things as safes and fowling-pieces, *see* pp. 250 and 273.

Digitized by Google

careful still and make a more critical examination ; but as ordinary houses they are safe so long as the conductors are in decent condition.

Now rapidly run over ordinary good orthodox conductors. First, the sky end. Points are good, as explained ; but platinum points are liable to be melted. The best points are cones of copper, not too sharp, and thickly gilt. Gold is better than platinum in being just as durable and much better conducting, and therefore less liable to melt. Many points are better than one, especially as some are apt to get fused and blunted by some discharge ; others may still remain sharp.

True, anything will act as a point when the tension rises high enough ; but the great thing is to keep down these dangerous tensions if anyway possible. So soon as a knob begins to emit brushes the sparking point cannot be far distant ; but sharp points will glow and reduce the strain far before the sparking point.

Perhaps the best protected building in the world is the Hôtel de Ville at Brussels, the hobby of M. Melsens. The whole system used in this building is excellent and theoretically perfect, so far as I know, in every respect ; but it is not cheap, and some people might perhaps hold that it was not artistic.

As for the main conductors, one finds rod, rope, and ribbon. The plan most approved perhaps by the Lightning-Rod Conference is this copper-tape, which is very nice, neat, and flexible, and free from joints.

Two important matters to be thought of in connection with the conductor are—that it shall not corrode away in places, and shall not be stolen. Another point that must not be overlooked in fixing up any length of conductor is that it is liable to expand and contract. An allowance must be left for this. When it is remembered that it is liable to be exposed to the full glare of the sun, backed up sometimes by a kitchen chimney behind, and then again at another time exposed to the coldest nights, a range of 100° Centigrade is not excessive.

I once rigged up some copper rod battery conductors of substantial thickness between two walls, and one morning after a frost found one snapped clean in half by the contraction. This would be a bad thing to happen to a lightning conductor ; so either bends must be left in the rope when put up, or else special compensators must be introduced at intervals.

The allowance for copper is 1 in 500 ; say an inch in every 40 feet. The best place for a compensator is just above the holdfast, so that it will have to support no weight. A bight or bend in a flexible rope answers every purpose, but bends should not be made too sharp, or the discharge will jump across instead of going round. That is a thing to be remembered. Flexible conductors are very convenient, but their convenience must not be abused. Always take them as straight as possible. Lightning has no time to go round circles—it will jump across sooner. Why should it not be let to jump across ? Well, because it burns the conductor. That is the real objection to bad joints—the extra heat ; a sort of arc produced there, and the liability to fusing and destruction of the conductor at these parts. There is, moreover, some danger from fire.

Now about the earth end. We have had examples of good earths already. Here is a cheap one advocated by Dr. Mann : wire rope opened out into a brush, and the two ends of another short bit, similarly treated, spliced across the first. Two of the fuzzed out ends make contact with deep soil, one with the surface soil, so that one or other is pretty sure to reach moisture.

The whole conductor introduced into the Cape by Dr. Mann, is simple, cheap, and admirable for cottage purposes and for emigrants. Squatters in the States, or Canada, or at the Cape, are far more liable to thunderstorms than we are in this country, and they should certainly rig up one of these homely things. A bit of iron fencing rope will do, with both ends fuzzed out, one supported by a tube fixed to the chimney, the other sunk deep into moist ground, or swamp if available.

In towns, where there are water or gas mains anywhere near the terminus of a lightning conductor, they should always be connected to it ; and this mainly for their own protection. For if they be not connected, the lightning will not scruple to still make use of them if it chooses, and having to jump across a yard or two of bad conductor on the way, it can easily knock a hole in them or melt them, instead of getting to them quietly.

It must be understood that what I say of the mains underground does not apply to the pipes in a house. To connect lead water pipes with a lightning-conductor might possibly lead to their being melted ; but to connect the house gas-pipe with a conductor is a most dangerous proceeding. The neighbourhood of gas-pipes in a house must be scrupulously avoided. The more it is connected to the mains underground the better, but one does not want lightning rushing along compo-pipes, picking out all the bad joints, and lighting all the gas there. In so far as a house contains escaping gas, or weak gas-pipes, it must be treated like a powder magazine, and great care be taken. A ridiculously minute spark may ignite gas without being noticed, the hole in the pipe may quietly enlarge, and the house be burnt down. A considerable amount of damage has been done in this way. So soon as Swan lamps are in universal use, lightning may occasionally play havoc with their filaments and fuse a few cut-outs, but it will not find the leads easily combustible or capable of burning the house down.

Whether it be gas or electric light, however, lightning should, if possible, ke kept out of the house-leads—not only because of the danger it may do at joints and insulations, but because the gas-brackets and chandeliers are usually conveniently suspended over desks and near arm-chairs, just where an unsuspecting person's head is likely to be ; and a spark to one's head is unsafe.

Hitherto I have spoken of the orthodox system of protection, the gather up and carry away system. But, as you know, there is another system suggested by Clerk Maxwell, the birdcage or meat safe principle. In a banker's strong room you are absolutely safe. Even if it were struck nothing could get at you. In a birdcage, or in armour, you are moderately safe. I should not care to try armour myself ; the joints might get unpleasantly hot and explosive. And even the birdcage, if struck by a big enough flash, might get melted. A melted patch on one's protective armour would be extremely disagreeable. Sometimes one is told to get thoroughly wet through instead of seeking shelter in a thunderstorm ; but it is a question whether a stroke is more unpleasant than rheumatic fever.

However, a sufficiently stout and closely-meshed cage or netting all over a house will undoubtedly make all inside perfectly safe. Only, if that is all the defence, you must not step outside, or touch the netting while outside, for fear of a shock. It would be unpleasant, when you reached home out of a storm, to find it so highly charged as to knock you down directly you tried to go in. An earth connection is necessary as well.

A wire netting all over the house, a good earth connection to it at several points, and a plentiful supply of that barbed wire which serves so abominably well for fences stuck all over the roof, and you have an admirable system of defence.

Now let us see how far most people agree, and where they begin to branch out and differ. The old and amusing political controversy between knobs and points has disappeared. Points to the sky are recognised as correct ; only I wish to advocate more of them, any number of them, rows of them, like barbed wire—not necessarily at all prominent—along ridges and eaves. For a point has not a very great discharging capacity. It takes several points to discharge readily all the electricity set in motion by a moderately-sized Voss or Wimshurst machine ; hence, if you want to neutralise a thunder cloud, three points are not so effective as 3,000.

No need, however, for great spikes and ugly tridents, so painful to the architect. Let the lightning come to you, do not go to meet it. Protect all your ridges and pinnacles, not only the highest, and you will be far safer than if you built yourself a factory chimney to support your conductor upon. At present the immediate neighbourhood of a factory chimney or steeple is not a safeguard, but a source of mild danger. But no one need believe this till after my next lecture, and not then if the experiments fail.

Next, as to the conductor. Should it be iron or should it be copper ? Should it be insulated from the building, or should it be connected with all the metal it contains ? These are questions at present in dispute. The Lightning-Rod Conference approves copper, though not putting it specially and strongly before iron. Durability is its main recommendation. Under all circumstances I am not sure whether it is more durable than galvanised iron. Mr. Preece has great experience of wires in chemical and all other districts, and I believe he upholds iron. Franklin and the Americans to this day prefer iron. Certainly it is much cheaper, and not so easy to melt. We will consider the question, and, I think, come to a definite conclusion next week.

Also the question about connecting up the conductors to all metal masses, roofs, girders, balconies, water gutters, &c. ; we had better leave that open too. Nearly everyone condemns insulators, but one eminent authority, M. Callaud, advocates caution and circumspection in what things you connect and what you do not connect. He points out, for instance, that if you connect up a balcony to the conductor, a person standing thereon may become one of its striking terminals. I must say I agree with him. Some there are who advocate connecting *both* ends of a roof gutter, or other such nearly closed contour, and not only one end. I decidedly agree with this also, for reasons which next week I will make abundantly clear. On this point I have, in fact, no doubt.

As regards the shape of the conductor, whether rod or ribbon ? Many experiments have been made, notably some by Mr. Preece on the discharge of Dr. De la Rue's battery through conductors of various sectional shapes, to see if extent of periphery matters. Hitherto the results have been negative. We may conclude, I think, that it does not matter much as regards liability to be deflagrated. But theory clearly points to the fact that a bundle of detached wires is electrically better than a solid rod of the same weight per foot, in every respect except durability. But durability is an essential feature. No shape can be considered satisfactory which aids corrosion. One thing is obvious ; plenty of surface

Digitized by Google

encourages cooling, and slightly diminishes danger of melting. Its other much more important advantages we will consider later.

Lastly, the "earth" and its testing. An earth is necessary, or you will have your foundations knocked about and your garden ploughed up. A good earth is desirable. A few tons of coke with the conductor coiled up amongst it is a well-known and satisfactory plan if the soil be permanently damp. A bag of salt might, perhaps, be buried with it to keep it damp throughout, or rain water may be led there. Often, however, the most violent thunderstorms occur after a spell of fine weather, and the soil is likely to be dry. It is the best, therefore, to run your conductor pretty deep, and there make earth.

It is all very well to connect the conductors to water-mains if near, but if they are far off or non-existent it is no use; and in no case, in my opinion, should they be used as sole earths. Certainly not gas-mains. In dry weather they are not earthed at all well, and a strong charge may then surge up and down them and light somebody else's gas in the most surprising way. It does not often happen, but it may happen in sandy soil after dry weather. Always there should be a good deep earth—a well if possible, a boring if not—and the conductor be led down into it. If it likes to make a disturbance when it has to leave the conductor a long way down, no one need grumble. It cannot do much harm there. There is, of course, no magic in water, unless it forms a large continuous sheet. An isolated puddle in a rock, such as has been used before now for a lighthouse, is no earth at all. A thoroughly good earth is really a geological question; and for an important building a geological specialist should be consulted.

An occasional test of an earth, in ordinary weather, is no real security as to what may happen after a long-continued drought. It would be easy to arrange a plan whereby just raising a handle shall give sufficient information as to the state of the earth, without any skilled operator. To this end two earths should be provided, quite independent of each other (one a water-main, for instance, the other a ton of coke), and they should be connected, first to each other and then to the conductor, by a substantial copper band. Now, let the band connecting the two earths pass through some covered outhouse, and have a well overlapping junction of two flat areas pressed together by a spring, but capable of being raised on or off the other by pulling at a handle or a rope. A galvanometer indicator and Leclanché cell, permanently connected so as to send a current between the two earths directly the handle is raised, will show by its deflection the state of conductivity of the two earths. Very likely the two earths themselves will suffice to give the necessary current without an auxiliary battery.

There is this to be said, however. If a building is so situated, either on high sandy ground or on an impervious rock, that a decent earth is very difficult to get, then, at least, the house is not likely to make a better earth than the conductor. That is a weak point in the excuse so often made concerning an accident to a protected building, that the earth was not sufficiently good. It can very seldom be shown that the earth, apparently chosen in preference, was any better; often it was obviously worse.

It is a superstition to place much reliance on the testing of conductors with a galvanometer and Wheatstone bridge. A galvanometer and Wheatstone bridge are powerless to answer many important questions. A Leclanché cell can no more point out what path lightning will take than a trickle down a hill-side will fix you the path of an avalanche. The one is turned aside by every trivial obstacle, and really chooses the line of least resistance; the other crashes through all obstacles, and practically makes its own path. A flash strikes a house at one corner, rushes apparently part way down the conductor, then flashes off sideways to a roof-gutter, sends forks down all the spouts, and knocks a lot of bricks out. Another branch bangs through a wall in order to run aimlessly along some bell-wires, and then out through a window-frame, and down a spade or something propped up against the wall to earth. The lightning tester comes with his galvanometer and Leclanché cell, and reports that the earth of the conductor has 100 ohms resistance; and the accident is therefore accounted for. But how much resistance would he have found in the paths which the lightning seemed to choose in preference to the 100 ohms? Something more like a 1,000,000 probably. Or, perhaps, there is a bad joint in the conductor somewhere, the parts being separated by one-sixteenth of an inch. But why should it prefer to jump several yards, and knock holes in walls and windows, rather than jump one-sixteenth of an inch? No; the galvanometer, and Wheatstone's bridge, and Ohm's law, and conductivity, are simply not in it.

Something has been left out of consideration, and something very important, too; and until that something is fully taken into account no satisfactory and undeniable security can be guaranteed.

That something is inertia—electrical inertia.

Suppose you have a pipe or U-tube full of water, used as perpetual overflow to a cistern, and you want it to be equal to all demands. You test it, and find it perfectly easy to pour the water either way; both ends are perfectly open; the pipe is a good conductor. Then comes some one and hits the stagnant water in your pipe a tremendous blow with a hammer, bursts the pipe, and scatters the water all about. That is what lightning does to your lightning conductor and to the electricity in it. It is no great push, it is a terrific blow.

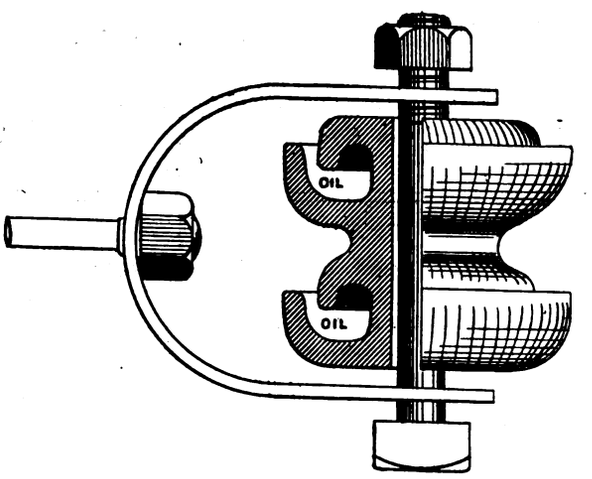
Conductivity is not what you want; widening the pipe is no remedy. There is a something you want; there is a remedy. The remedy is elasticity—electric "capacity." You must reduce the electrical inertia (or self-induction) of your conductor as much as possible, and you must increase its electric elasticity (or capacity) wherever convenient. These are matters concerning which I have many experiments to show next week.

The lecturer exhibited a photograph of Sanderson's climbing ladder for chimneys, which had been kindly lent by Messrs. Richard Anderson and Co. He read (as requested) a letter from Mr. W. McGregor, advocating the formation of a society for the protection of life and property from lightning. And he called attention to a suggestion of the Hon. R. Abercromby's, at the Manchester Meeting of the British Association last year, that a systematic observation and record of thunderstorms should be undertaken, so as to gain a knowledge of the distinct types of storm, and the modes of circulation of air which accompany them.

He further desired to express his obligation to the following books, for many details and examples of damage done, and of current methods of protection:—"Lightning Conductors," by R. Anderson, third edition, revised by Dr. Mann (Spon). "The Thunderstorm," by C. Tomlinson, F.R.S. (S.P.C.K.). "Report of the Lightning-Rod Conference," edited by G. J. Symons, F.R.S. (Spon). An extensive list of memoirs on the subject is contained both in this Report and in Anderson's book. Dr. Mann's Paper in the *Journal* of the Society of Arts, 1875 and 1878.

AN OIL INSULATOR FOR SHACKLES.

We illustrate herewith a form of fluid insulator adapted for shackles, which has been designed by Mr. F. Higgins, and is used on the lines of the Exchange Telegraph Company. The sketch needs very little description. It will be seen that there are two oil cups, and that externally the shackle is of much the usual form. Since the use of fluid insulators was first introduced by Messrs. Johnson and Phillips, their great value in cases where high insulation is required, or where exceptional difficulties are met with in maintaining insulation, has been repeatedly recognised. For over-house electric light wires some use has already been made of this form of insulator, and for such a purpose Mr. Higgins's shackle will often be very useful.



MEETINGS OF SCIENTIFIC SOCIETIES.

SATURDAY, June 23rd.

PHYSICAL SOCIETY.

8 p.m. Note on "Continuous Current Transformers." By Prof. S. P. THOMPSON, D.Sc.

WEDNESDAY, June 27th.

SOCIETY OF ARTS.

4 p.m. Annual General Meeting.

SOUTH OF ENGLAND TELEPHONE COMPANY (LIMITED).—The directors of this company, at their meeting to-day, decided to recommend a dividend of ½ per cent. on the Ordinary share capital for the year ended 30th April last, placing £500 to a reserve fund, and carrying forward £1,115. 0s. 8d. The dividends on the Preference Shares have already been paid.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* THE PROPRIETORS.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	4 11	9 9	19 6

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

SPECIAL NOTICE.

We shall be glad if those of our readers who obtain copies of the "ELECTRICIAN" through newsvendors will bring to our notice any case in which leaflet advertisements of an objectionable character are inserted in the paper. No advertisement leaflets of any kind are ever inserted at this office, and newsvendors inserting such leaflets render themselves liable to prosecution.

THE ELECTRIC LIGHTING ACT AMENDMENT BILL.

In the House of Lords on Monday last the Commons' amendments to Lord THURLOW's Bill for amending the Electric Lighting Act of 1882 were agreed to, and by the time these lines are in print the measure, as now amended, will probably be the law of the land. The draughtsman of the original Act, departing from the usual phraseology in such documents, applied the term "undertakers" to those persons who, in similar relations, had previously been described as "promoters." Whether this was a happy inspiration or an unintentional prophecy, certain it is that a funereal aspect has clung to the Act ever since its promulgation, the undertakers undertaking nothing except to bury it in oblivion so soon as its real character was understood. For a few brief weeks after the passing of Mr. CHAMBERLAIN's Act applications for licenses and provisional orders poured in upon the Board of Trade with quite unexpected abundance; but long before the bye-laws under which they were to be granted had been drawn up every one of these applications had been withdrawn, or the projects with which they were connected virtually abandoned. The interval of six years which has elapsed since then has made no change in the disposition of the undertakers, not one of whom has attempted to exhume the Act from its unhonoured grave. On the contrary, in every succeeding year the demand for an amended Act, or, in other words, a radically different Act, grew stronger; and this has at last resulted in the legislative concession which we are able to announce to-day.

The question here naturally arises—What shall we do with it now that we have got the amendment so long desired? On the whole, we may say that comparatively little interest has been taken in the matter by the electric lighting companies, whom we prefer to call promoters, the chief anxiety being manifested by the general public and the newspapers which represent their views. This is a hopeful sign, for it indicates, on the one hand, that the demand for the electric light has become too strong for the legislative obstacles thrown in its way; and, on

Digitized by Google

the other, that the business of electric lighting is being carried on successfully in spite of and without the help of any legislation whatsoever. We have always thought that the discipline of these years of free competition would operate beneficially on the industry, and we are still of this opinion, whatever may follow from the passing of Lord THURLOW's Bill. That Bill, as it stands, although a great improvement on its predecessor, is by no means wholly satisfactory, and the time which has been occupied in doing without it has proved that if they are not acceptable to the investing public the provisions of the Bill can be dispensed with without serious hindrance to the trade. It is probable, however, that in many instances they will be taken up with alacrity. There is abundance of capital awaiting investment; there is a considerable demand for the electric light; and with the experience gained during the period of probation there is no reason to doubt that the terms offered under the new Act will attract investors and prove fairly remunerative.

Some of the more glaring objections incidental to the original Act arose out of the regulations which the Board of Trade was empowered to frame for its administration. The absurdity of some of these rules was pointed out by Mr. T. H. BLAKESELEY soon after they were issued; and it is hardly necessary to add that they have never been put in force, nor ever will be. Some damaging criticisms had been made by the Secretary of the Edison Company earlier in the year following the passing of the Act, on the restrictions as to the lamps to be used and the manner in which the consumer was to be charged. The companies were left no option; and as lamps were capable of great improvement, Mr. ARNOLD WHITE not inaptly described the Act as one for the perpetuation of bad lamps. He also pointed out the inadequacy of the inspection proposed by the Board of Trade in the supposed interest of the consumers, the companies at that time being of opinion that the inspector should examine and test the light supplied, and not the methods employed for supplying it. Probably on these and a number of other points which were taken exception to at the time, the Board of Trade, as well as the electrical engineering profession, have learnt a great deal since then, and we shall expect that the regulations under which the Act of 1888 will be administered may at least be workable or be capable of becoming so. When these preliminaries have been adjusted, there will probably be little delay in applying for provisional orders on the part of local companies, many of which will no doubt be formed to employ special systems identified with well-known firms. We do not suppose that these firms will become promoters under the Act on their own account to any large extent. The lessons of 1880-2 ought to be sufficient safeguard against the unnecessary assumption of speculative risks, at any rate so long as a safe and fairly extensive business can be done in the manufacture and erection of plant.

As regards the municipalities, it is probable they will largely avail themselves of the option afforded them by the Bill, and the confidence which the passing of it will naturally inspire. The Local Government Bill, if it survives the ordeal it is now undergoing, will also contribute to this result by increasing the powers and responsibilities of the local authorities. The original Electric Lighting Act was no favourite with the municipal bodies. As we remarked soon after it was passed, the Act conflicted with their most cherished views of local self-government, the whole power of the local authorities in regard to the supply of electricity being transferred by a side-wind of legislation to the political Secretary of the Board of Trade. A strong remonstrance from provincial local bodies was made at the time; and it is not to be supposed that with the virtual independence they will enjoy under Mr. RITCHIE's Bill they will long submit to the dictation of the Board over which he now presides. Under the old Act it was possible to compel the local authorities to adopt the electric light by the threat of granting a license to an outsider. The outsider, as things happened, did not present himself; but even if the same power is retained in the new Act, the Board of Trade will be slow to exercise it, and the local authorities will be none the less likely to look kindly on the electric light for being perfectly free to adopt it or not as they please. They were distinctly hostile to Mr. CHAMBERLAIN's Bill; so far as we can learn they are, on the whole, by no means unfriendly towards Lord THURLOW's. Naturally they did not at first approve of the terms of purchase in the amended Act; but, so soon as they discovered that they must have this or nothing, their opposition was withdrawn.

DELANY'S SAFETY DEVICE FOR LINEMEN.

BY C. W. S. CRAWLEY AND H. NALDER.

A short time ago Mr. Delany read a Paper before the American Institute of Electrical Engineers on the protection of the human body from dangerous currents, and suggested the use of metallic wristlets and anklets, all four of which were to be joined by a wire. Thinking it would be well to determine how far this method really afforded protection, we recently made a few rough experiments on the subject. Round each wrist was wrapped a strip of tinfoil 7·5 cm. wide, and this was bound on with a piece of copper wire; the wrists were well wetted with salt water, and an exceptionally good contact was thus obtained. The palms of the hands were placed on metal plates in earthenware dishes, which were then filled with water containing common salt, so that the palms of the hands were wetted but not the backs. The hands were kept as still as possible the whole time on the metal plates, so as to avoid any variation of surface, and therefore of resistance, and switches were arranged so that the current could be put on to either the metal plates or the wristlets.

It was required to measure the following:—x the resistance of the body apart from skin resistance, y the skin resistance of a hand, and z the skin resistance of a wrist. The measurements were made by a delicate voltmeter used as an ammeter. Used in this way its constant came out ·05 milliampere per degree, the total E.M.F. applied being measured by another voltmeter. The first E.M.F. used was 18 5 volts. Four measurements were taken—

(*a*) Left hand to right hand,
(*b*) Left hand to right wrist,
(*c*) Left hand to left wrist,
(*d*) Left wrist to right wrist,

the resistances in these cases being respectively $x+2y$, $x+y+z$, $y+z$, $x+2z$, from which, of course, it is easy to get the values required, the last measurement being taken merely as a check. Five sets of readings were taken with 18·5 volts, and five more with 11 volts. The hand resistance, as might be expected, fell considerably with time, beginning with 1,000 and falling to 395; z, however, rose from 770 to 1,165, which may be accounted for by the skin drying to some extent under the wristlets, though when the latter were taken off the skin was still found to be very appreciably damp. In each set of experiments the measurements were taken as quickly as possible one after the other, so as to prevent change during the set. The mean values found, with 18·5 and 11 volts respectively, were $x=675$ and 930 ohms, $y=695$ and 470 ohms, $z=785$ and 1,035 ohms. Bringing these figures to bear on what would occur in practice it comes to this: the current enters at the hands and gets through to the inner tissues; arriving at the wrists it has two paths open to it, one through the body, with a resistance of about 800 ohms, the other through the short-circuiting wire + twice the skin resistance of the wrist (or $2y$), which is somewhere between 1,600 and 2,000 ohms—that is, it would at best only relieve the body of about $\frac{1}{3}$ the current; while in actual practice, with the skin comparatively dry, we should be sorry to trust to it to do as much as this.

Digitized by Google

One further negative result may be mentioned: with 18 volts, and the current on the two hands, the reading was 179 degrees; the two wristlets were then metallically joined together, and the current only rose to 180°, or 9 milliamperes. This last result, though obviously not consonant with the resistances measured, was observed several times.

THE MINIMUM POINT OF CHANGE OF POTENTIAL OF A VOLTAIC COUPLE.*

BY DR. G. GORE, F.R.S.

In a previous communication on "The Effect of Chlorine on the Electromotive Force of a Voltaic Couple" (Roy. Soc. *Proc.*, May 3, 1888) I described a phenomenon which I now venture to term the "Minimum Point of Change of Potential of a Voltaic Couple." In that description a "thermo-electric pile" is mentioned as having been used for the purpose of balancing the electromotive force of the couple, whilst finding the "minimum point of change." As very few persons possess a thermo-electric pile suitable for the purpose, I have devised and employed the following arrangement, by means of which the use of the pile may be dispensed with.

Take a voltaic couple, composed of an unamalgamated strip or stout wire of zinc or magnesium (the latter is usually the best), and a small sheet of platinum immersed in distilled water; balance its electric potential through an ordinary galvanometer by that of a precisely similar couple composed of portions of the same specimens of the same metals, immersed the same moment as the other pair in a separate quantity of the same water, and gradually add to one of the two cells sufficiently small and known quantities of an adequately weak solution of known strength in a portion of the same water, of the substance to be used, until the balance is upset, and take note of the proportions of the substance and of water then contained in that cell. It is more easy to successively dilute than to successively strengthen the solutions, and thus arrive at the "minimum point." The method is a little less accurate than the one in which a thermopile is employed.

By means of this method, using a couple composed of magnesium-platinum in distilled water, I have found the following "minimum points of change of voltaic potential" in solutions of potassic chloride, potassic chlorate, hydrochloric acid, and chlorine. I selected these substances because they were representative ones suitable to yield results for comparison, and because they gave extreme and intermediate magnitudes of the effect. The results are compared with those obtained with a Mg + Pt couple and the thermopile.

Potassic Chloride KCl.—Solution at 18°C., "minimum point" lay between 1 part in 3,875 and 4,650 parts of water, and by the aid of the thermopile, with the solution at 17°C., "minimum point" between 1 in 3,875 and 4,305.

Potassic Chlorate $KClO_3$.—Solution at 19°C., "minimum point" between 1 in 4,650 and 5,166, and with the pile, solution at 18°C., between 1 in 4,920 and 5,470.

Hydrochloric Acid HCl.—Solution at 17°C., "minimum point" between 1 in 516,666 and 664,285, and by the aid of the pile, solution at 19°C., between 1 in 516,666 and 574,074.

Chlorine Cl.—Solution at 18° C., "minimum point" between 1 in 15,656,500,000 and 19,565,210,000, and with the pile, solution at 12·5° C., between 1 in 17,000 millions and 17,612 millions.

The results show the great degree of delicacy of each method, and the extremely large difference of proportion of different substances required to upset the balance. The two methods agree.

By employing a great variety of dissolved substances I have found that nearly every such substance has a minimum proportion, below which it has no apparent effect upon the electromotive force of a Mg Pt or Zn Pt couple in distilled water; and this proportion appears to be a constant number, dependent only upon very simple conditions, viz., unchanging composition of the voltaic couple and liquid, a uniform temperature, and employing the same galvanometer. The apparently constant numbers thus obtained may probably be used as tests of the purity or of the uniformity of composition of dissolved substances.

The "minimum point" and degree of sensitiveness varies with—1st, the chemical composition of the liquid; 2nd, the kind of positive metal; 3rd, to a less degree with the kind of negative metal; 4th, the temperature at the surface of the positive metal, and at that of the negative one; and 5th, with the kind of galvanometer employed.

The order of the degree of sensitiveness or magnitude of the "minimum point" is manifestly related to that of degree of chemical energy of the liquid, and, therefore, also to the atomic and molecular weights of the dissolved substances, and to the ordinary chemical groups of halogens. With certain exceptions, it is also distinctly related to the amounts of chemical heat. The greater the degree of free chemical energy of the dissolved substance, and the greater its action upon the positive metal, the smaller the proportion of it required to upset the balance. The proportion necessary for this purpose probably represents a fixed amount of voltaic energy in all cases, viz., the amount necessary to overcome the mechanical inertia of the needle of the particular galvanometer employed.

As the "minimum point" of a chemically active substance dissolved in water is usually much altered by adding almost any soluble substance to the mixture, measurements of that point in a number of liquids at a given temperature with the same voltaic pair and galvanometer, will probably throw some light upon the state of combination and degree of chemical freedom of substances dissolved in water.

* Paper read before the Royal Society, June 14, 1888. Abstract.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER IX.—*Magnetic Fields.*

(Continued from page 148.)

114. *Action of a Magnetic Field on a Magnet.*—It has been mentioned before that when a magnetic needle suspended or pivoted about its centre is placed in a magnetic field, it immediately sets itself in the direction of the lines of force in that field—that is, the direction of its own internal lines coincides with the direction of the lines of the field at the point where it is suspended. It is important to understand fully this action, as it immediately concerns the cause of the movement of galvanometer needles when the field by which they are surrounded is altered by starting a current in the coils.

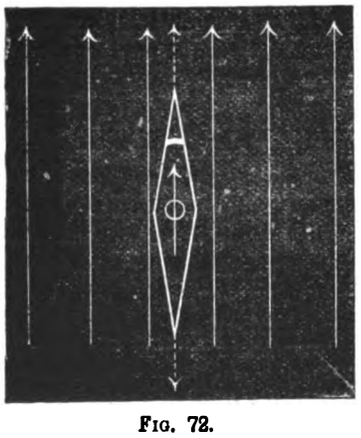

FIG. 72.

Let us consider a horizontally suspended magnetic needle free to move in a horizontal plane in the uniform magnetic field of the earth. It will set itself with its marked or north end towards the north pole of the earth, as in Fig. 72, where the straight lines represent the uniform lines of force of the earth's horizontal field H, and the arrow inside the magnet represents the direction of its own internal lines of magnetisa-

Digitized by Google

tion. The force acting at each end of the needle keeping it at rest in this position is equal to the product of H into the strength of the needle pole, which we call m; that is, the force at each end of the needle is equal to H m. This force is shown in dotted arrows at each end of the needle, and it will be seen that when the needle is in this position (the meridian) there is no *turning* force exerted on it. But now, if we turn the needle through a right angle, as in Fig. 73,

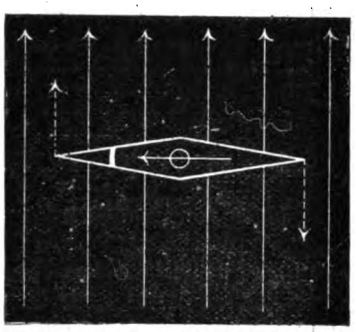

FIG. 73.

we shall have to exert some force to keep it there; in other words, the force H m at each end is now tending to turn it back to the meridian.

115. "*Moment*" *of a Force.*—The capability of a force to produce movement, or turning about a centre, is termed the "*moment*" of that force. The moment of a force about a point is the product of that force into its perpendicular distance from the point—that is, the distance from the point to where the force is applied must be reckoned along a line perpendicular to the direction of the force. To make this clear let us take a rigid bar, A B, capable of turning about its centre, C, at one end of which a force equal to F lbs. is pulling (Fig. 74) in a direction making an angle of a degrees with the bar. Let the bar be L feet long; the length A C will then be $\frac{L}{2}$ feet. Draw C D perpendicular to the direction of the force. The "moment" of the force about the point C is then—

F × perpendicular C D.

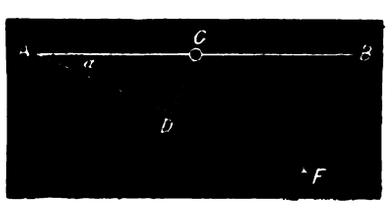

FIG. 74.

Now we can find the length of C D by a simple trigonometrical ratio. (It may be mentioned here that the only trigonometrical functions of angles made use of in these papers will be the three most frequently met with—viz., the sine, the cosine, and the tangent. The student should familiarise himself with these simple functions of angles. A table of natural sines and tangents will be required for reference. The cosine of an angle may be found from a table of sines by subtracting the angle from 90 and taking the sine of the remaining angle.) Now we have the ratio $\frac{CD}{AC} = \text{sine } a$; and therefore

$$CD = AC \sin a = \frac{L}{2} \sin a \text{ (feet)};$$

whence the moment of the force is equal to

$$F \times \frac{L}{2} \sin a \text{ (pound-feet)}.$$

For example, if F = 10lbs. and L = 10ft., and the angle = 30°, we have moment of $F = 10 \times \frac{10}{2} \times \frac{1}{2} = 25$ pound-feet (where sin $30° = \frac{1}{2}$).

It should be observed here that since sin $90° = 1$ and sin $0° = 0$ the moment of F is $\frac{FL}{2}$ when the force acts at right angles to the bar, and is *nil* when acting in the direction of the length of the bar. Hence a given force acts at the greatest advantage as regards turning a lever, or, in other words, its moment is greatest, when it acts at right angles to the direction of length of the lever. When we, for instance, exert force ourselves in order to move a heavy lever, such as the opening or closing of the gates of a river lock, we instinctively use our strength to the best advantage by pushing at the extreme end of the lever and at right angles to it. Taking the above figures with the force acting at 90deg., the moment of F becomes

$$\frac{10 \times 10}{2} = 50 \text{pound-feet.}$$

Suppose, now, that an equal force, parallel to the first, acts at the other end, B, of the lever (Fig. 75), so as to turn it round in the *same* direction about the centre C. Drop the line C D′ perpendicular to the direction of the force, as before. Then $\frac{CD'}{CB} = \sin a$, or $CD' = \frac{L}{2} \sin a$ (angle C B D′ $= a$), and therefore the moment of the force F acting at B is

$$\frac{FL}{2} \sin a,$$

which is the same as the moment of the force acting at A.

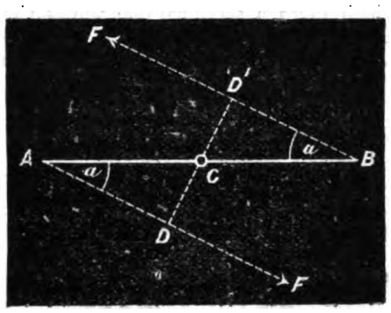

FIG. 75.

Now, as both these forces tend to turn the lever the *same* way round we must *add* their moments to obtain the moment of the two together, and as their moments are equal the moment of the two will be twice that of one—that is,

$$2\left(\frac{FL}{2} \sin a\right) = FL \sin a.$$

For example, with equal forces of 10lb. each, acting at each end of the lever at an angle of 30deg., the moment of the two forces combined is

$$10 \times 10 \times \tfrac{1}{2} = 50 \text{ pound-feet.}$$

If the forces were acting at right angles to the lever, as in Fig. 76, the combined moment would be simply

$$FL = 10 \times 10 = 100 \text{ pound-feet.}$$

(To be continued.)

"INFLUENCE MACHINES, FROM 1788 TO 1888."*

BY PROF. S. P. THOMPSON.

(Continued from page 183.)

Almost at the very same time, and quite in ignorance that any other inventions of this kind were going on, there were a series of beautiful machines brought out by Sir William Thomson. In 1867 or 1868 he was at work upon some of these. There is one shown here at Fig. 15. The field-plate in this machine is in the form of a metal box; there are two of these, one on either side of the rotating armature. The latter has carriers upon it, and there is a pair of neutralising springs to touch these carriers while they are under influence, and other springs, or brushes, to receive the charges that were brought round. You have all the same parts of the organism as existed in Belli's and in Varley's machines, only you have them arranged a little more scientifically. Sir William Thom-

* A Paper read before the Society of Telegraph-Engineers on May 31st, 1888.

Digitized by Google

son expressly draws attention, I think, to the spring contact, and he also speaks subsequently (this is a point I confess I do not quite understand) of the great power of Holtz's machine as being due to the absence of the metallic carriers which he himself and others had been employing. This machine Sir William devised to serve as a "replenisher" for his quadrant electrometer, though very soon the more compact form of replenisher, with two narrow brass strips as carriers (Fig. 16), was substituted for that with the disc armature. The model here, 11in. in height, is a self-charging machine, differing only in size from the actual electometer replenisher. It was constructed by my assistant, Mr. Rousseau.

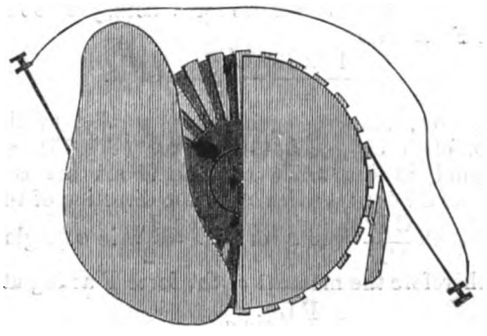

Fig. 15.—Sir W. Thomson's Replenisher (disc form).

In Fig. 17, which gives a sectional diagram of the replenisher, F F are the field plates, C C the carriers, $n\,n$ the neutralising brushes, and $a\,a$ the appropriating brushes, which receive the

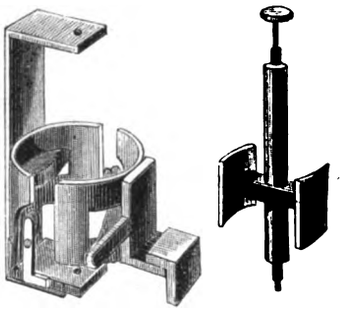

Fig. 16.—Sir W. Thomson's Replenisher, used in his Quadrant Electrometer.

charges as they come round on the carriers. I think, however, I shall do a very great injustice to Sir William Thomson if I let you imagine that that was his only machine. He has been kind enough to lend me for exhibition here two other

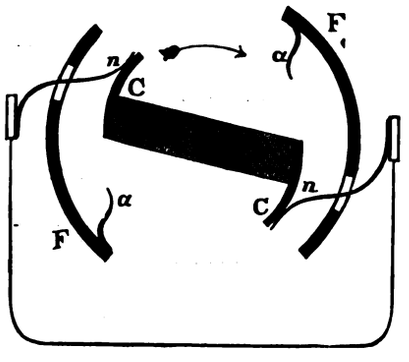

Fig. 17.

machines. They are interesting as being machines with rotating carriers and multiple field-plates, of a pattern which he devised for electrifying the ink vessel of the siphon recorder. I do not know whether these two actual instruments were early or late in the history of development, but they are very interesting—particularly interesting to me, inasmuch as they carry out an analogy which I have often dwelt upon between the influence machine and the dynamo. The lower field-plate is in position here underneath; the upper field-plate is a sort of cover to the machine—it has been removed so that you can see the armature. Now, from each row of the various sectors of the armature there comes out (insulated, of course) a metal pin. These metal pins stand out at the end like the parallel bars of the commutator of a dynamo—in fact, this is the commutator of the machine; and there are two pairs of metallic brushes, which rest on these commutator bars and take up

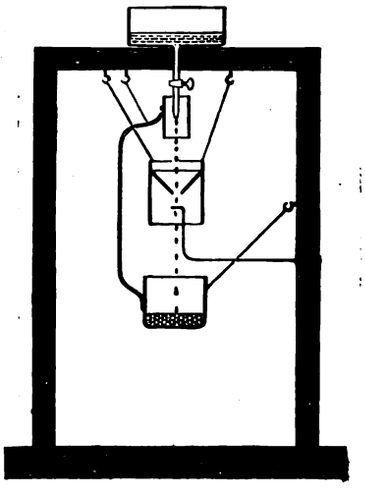

Fig. 18.—Modified Water-dropping Influence Machine.

the discharge just exactly as the brushes of the dynamo do. You can hardly have a more beautiful instrument on which to trace out the analogy between the influence machine and the dynamo. This

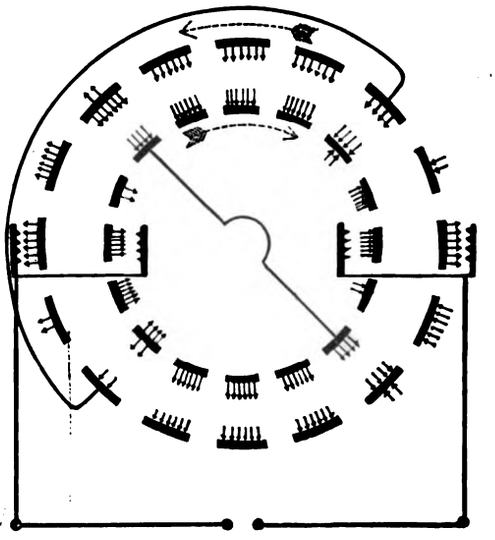

Fig. 19.—Diagram of Action of a Wimshurst Machine.

machine, known, I believe, as the "mouse-mill," and the "replenisher," and the "potential equaliser" are, however, not nearly

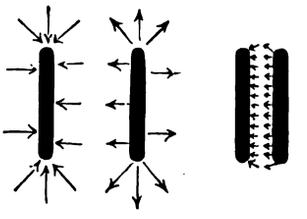

Fig. 20. Fig. 21.

all of Sir William's influence machines. There is one in which, without any rotation or any parts to rotate, he employed exactly all these principles—the touching of a carrier under influence and the reciprocal action from positive to negative. I have a rough model here of this most curious instrument. It looks very unlike the other instruments; it is the "water dropper." Here are two cylinders, and water might be arranged to drop in drops from nozzles through the cylinders; if the cylinders are electrified the drops will, in the act of dropping from the nozzles, be virtually touched while they are under influence. They thus drop through

Digitized by Google

the cylinders electrified with charges opposite in sign to those of the cylinders through which they respectively fall. The drops which fall through the positive cylinder give up their negative charges to increase that on the negative cylinder, while those that fall through the negative cylinder acquire positive charges which go to increase that on the positive cylinder. There are also some Leyden jars to stand thus and receive the accumulated charges. A few months ago I thought it might be convenient to simplify the pattern somewhat, and here is a much more portable form of Sir William Thomson's water-dropper which I have described in the *Philosophical Magazine* (Fig. 18). The water drops here through a cylinder at the top into a second cylinder, and then it drops from this, being touched in the act of dropping, by a wire underneath, while under influence, into a third, a mere can to catch the water, and which is connected metallically to the top cylinder. The insulation is effected by means of well-paraffined silk strings supporting the cylinder and the can.

Meantime improvements came about in other directions. The difficulties that were found in the construction of Holtz's machines led to various suggestions in detail. In 1886 Prof. Morton, of New York, proposed to replace the Holtz plate, with its windows, by pieces of glass coming up from four sides. Similarly, about 1881, when Mr. Wimshurst was thinking of the problem of the influence machine, it occurred to him that the best way to make those windows in the Holtz machine was to take two separate pieces of glass and fix them a little apart from one another, with the paper field-plates pasted on behind. That, indeed, was the beginning of Mr. Wimshurst's researches. His first step was to adopt this small improvement. There is here a small 12-plate Holtz machine devised at that time by Mr. Wimshurst on this plan. Then certain things suggested to his mind that it would be better to make both plates go round, and to make them go round in opposite directions. That idea was soon put into shape, and we have here the original machine exactly as it was the day that it was completed—a pattern which has hardly been altered even in the most recent of Mr. Wimshurst's machines. The two discs are driven in opposite directions. There are two sets of neutralising brushes going across diagonally front and back opposite quadrants, and there is a pair of discharging knobs. This machine charged itself the first time it was tried, and now charges itself as I turn the handle. From time to time other patterns embodying the same idea have been produced. Mr. Wimshurst has kindly lent me a machine with two rotating cylinders, one inside the other, a pattern which has lately been made up differently with ebonite cylinders.* I have here a larger machine, by Mr. Wimshurst, which he has kindly lent me. It has four pairs of rotating plates. There is no trouble about exciting this kind of machine ; it excites itself with a very small number of turns of the handle. Now, it has occurred to me that it may be useful to have a somewhat different method of representing the facts than has hitherto been common. The method of representing the action of a machine by drawings such as depict the parts as sections of a cylinder is due to Bertin. I have used it here in a diagram, in explaining Clarke's gas lighter for example. It has occurred to me that it was better to have some kind of a drawing in which one would be able to study, not simply the charges on the surfaces of the conductors or the conducting parts, but also the action in the space between ; because, after all, that is the really important thing. Therefore I have devised a diagram (Fig. 19) to represent the facts of the distribution development of the charges in a Wimshurst machine. Those two circles of black marks represent the two sets of metallic sectors or carriers on the two rotating plates ; each plate, front and back, has its set of carriers. Here they are represented as one being outside the other, and as this is drawn the inner set must be considered as going round right-handedly and the outer set as going round left-handedly. Now, consider what would be the result if a sector at any point possessed a positive charge. It will exercise an influence all round it. You will have lines of electric force proceeding from it into the field. I have not attempted to draw these lines, but I have attempted to suggest them. If you have an insulated charged conductor in the middle of a space its electric lines may be considered as radiating out in all directions. If you have a disc charged—say, positively—from every unit of the charge on its surface there will go out lines of electric force in different directions. Suppose you have a negatively-charged plate, you will also have lines coming in from different directions. In Fig. 20 I suggest that there are two insulated metal discs, seen edgeways, one charged negatively, the other positively, at some distance apart. The charges are distributed most strongly at the edges of the discs, but also to some extent on their flat surfaces. In Fig. 21 the same two discs are represented as having now been put close together, with the result that their charges now act strongly upon one another, nearly all the lines of electric force being concentrated across the intervening layer of non-conducting air or glass. You have these positive and negative charges attracting one another, and accumulating on the two surfaces which are nearest together, the electric forces acting across the dielectric, which lies between.

I have chosen to represent the positive units by drawing arrows with their heads proceeding out from the surface, and the negative charges are represented by the arrow heads turned with the head inwards towards the charged surface.

Now, in the Wimshurst machine, to which this diagram with its two circles relates, some of the metal carriers are charged positively, others negatively. Consider the carrier on the back (or outer) set positively charged, and situated on the left at 45 degrees above the horizontal diameter. Opposite this positively-charged sector there is a metallic sector in the front (or inner) set, going across from left to right. As it passes it comes into contact with a brush of fine wires on the end of the diagonal conductor. This neutralising brush touches it while under influence. As a consequence there would be electric displacement taking place across that dielectric, and this metal plate will become negatively charged. As all the front (inner) sectors pass this point they go on over the top negatively charged, whilst for precisely analogous reasons the back (outer) sectors behind them on the right come over the top positively charged ; they have been touched by the other neutralising brush while under the influence of the negative charges on the front (inner) sectors. The sectors of each set, while acting as carriers of their own respective charges, act also as field-plates to influence the carriers of the other set. Further, while the positively and negatively-charged carriers are passing one another, their charges attract one another, and there would occur sparks across between them if it were not for the plates of glass which separate them. As each carrier comes up to be touched by the neutralising brush, there will be a rush of electricity down that conductor to the other

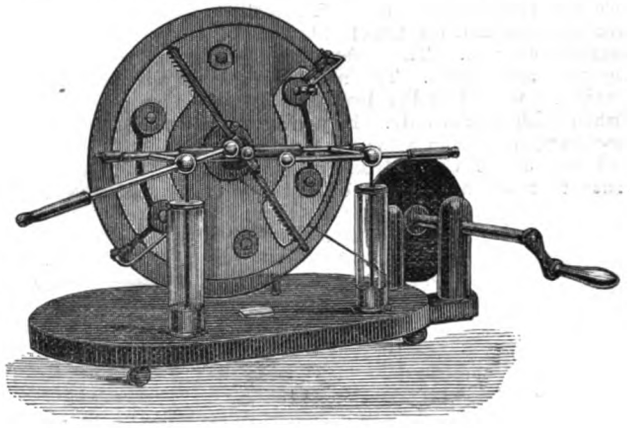

FIG. 22.—Voss Machine.

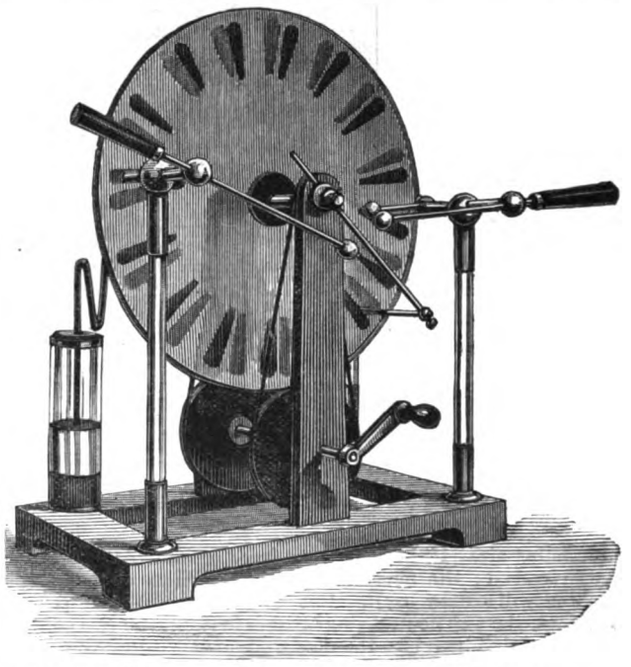

FIG. 23.—Wimshurst Machine (Harvey and Peak's form).

* See *The Electrician*, May 18th, 1888, p. 45.

Digitized by Google

end, where a similar action, but of opposite sign, is taking place. I have drawn my diagram as though each (back) carrier coming over the top from right to left brought a charge of 6 units of positive charge. Each carrier of the front (inner) set, as it passes under the neutralising brush at 45° above the horizontal on the left, is considered as having electricity driven out of it by the influence of these positive charges, and as being left in a state of negative charge to the amount of 6 negative units. In the lower half of the machine similar actions are going on, with the result that the positive charges are brought to the left side of the machine by both discs, whilst negative charges are brought by both discs to the right side. A pair of discharging combs face the two discs on the left side to receive the surplus positive charges, and on the right there is a pair to receive the negative charges. These combs are connected to the discharging rods and knobs. The neutralising rods are, as I have said, furnished with metallic brushes, the discharging rods are furnished with combs only. If you have only combs, as in Holtz's machines, and as in some of Varley's machines, those machines will not excite themselves. You require an initial charge in order to make a sufficient effect to produce a discharge across the same sign, and they will of course repel one another. Now, here is a piece of apparatus made by Mr. Wimshurst, which enables me to show you this in the most beautiful way. It is simply the mechanism of a machine with two plates, and with diagonal neutralising rods, furnished with brushes, front and back; but there are no discharging rods or combs. These discs are made, not of glass, but of that rather vague substitute *dermatine*, a composition of india-rubber, and I do not know what other materials, flexible, closely resembling leather. If I excite this machine the discs actually bend towards one another top and bottom, but bulge out away from one another on the right and left. Here is another form of Wimshurst's machine (Fig. 23), kindly lent for exhibition by Messrs. Harvey and Peak, who have themselves introduced some small but not unimportant improvements in the details of mounting the discs on the driving pulleys and in the form of brush holders. I will now invite your attention to this very large machine with twelve plates (Fig. 24), constructed and exhibited here to-night by Mr. Wimshurst. When I left it at six o'clock the handle was tied up, and it has not been moved since; it has been tied up all day. Therefore, there is no possibility of its having had any recent charge. I want you to see that this machine will excite itself, and I ask you

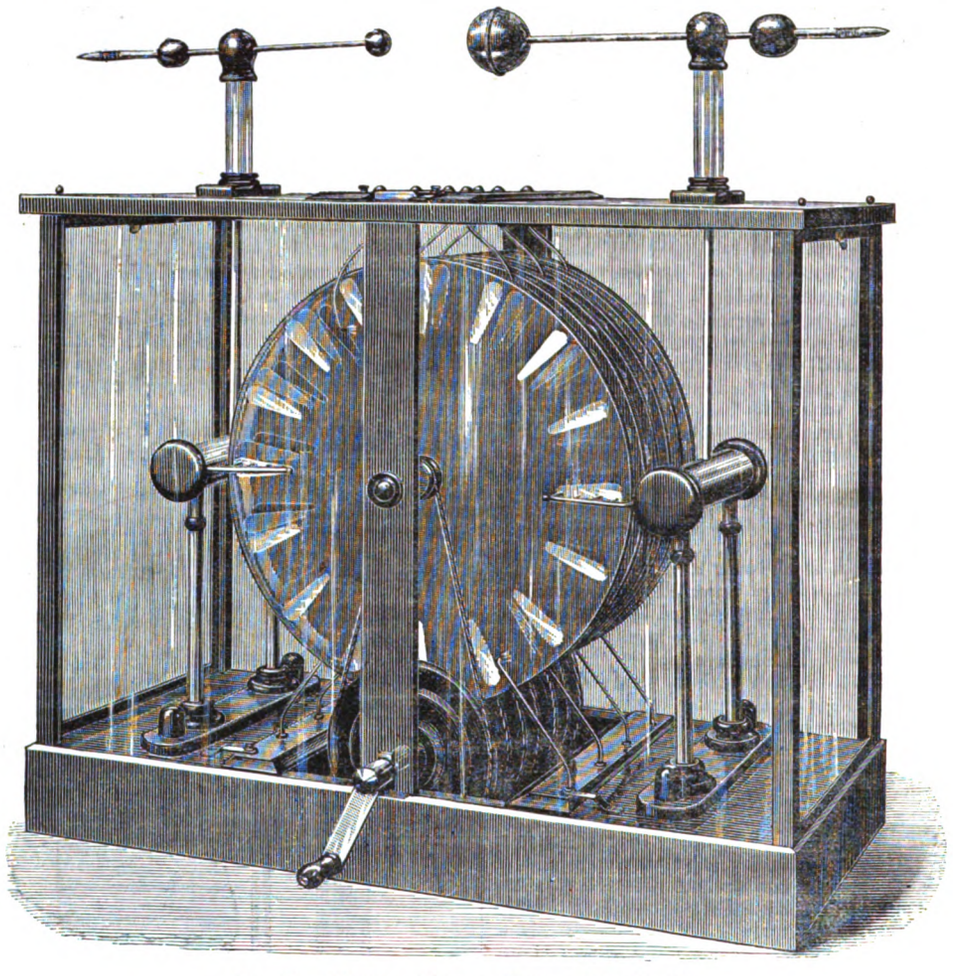

FIG. 24.—Wimshurst's large Twelve-plate Machine.

intervening air. If, however, you have brushes actually touching at the ends of the neutralising parts, then as a general rule the machine will excite itself. But if you have all the parts of the machines, the two neutralising brushes in front, the two neutralising brushes behind, and also the discharging apparatus, all made with brushes, the machine may excite itself; but then something else will happen. If you touch one of the discharging apparatuses so as to take a great discharge from one side, you are discharging through a metallic circuit, and you do more than you intend to do: you will probably reverse the machine in the very act of taking the discharge. You, therefore, ought not to have brushes, but combs, on the discharging part of the apparatus; and in all the recent examples of Mr. Wimshurst's machines—and for that matter I think in the latest Voss machines (Fig. 22), too—you will find that while the neutralising apparatus is provided with brushes, the discharging apparatus is provided with combs. I have already pointed out that in the region at the top, the two sets of carriers acquire charges of opposite sign, which attract one another. The same thing is true of the region at the bottom, but the respective signs are reversed. But at the sides, right or left, the charges of the two plates are of the to notice with what an extremely small amount of turning the machine does excite itself. I will take this very admirable electroscope and connect it on, and then I will turn as slowly as I can. You are to tell me when the machine excites itself. [Prof. Thompson here experimented with the machine, which had strongly excited itself when the handle had been slowly moved through about $\frac{1}{10}$ of a single revolution.] There is not much doubt about the power of that machine to excite itself; in fact, those machines, made as they are with good metallic connections for the two neutralising circuits that constitute the real working part of the machine, never fail to excite themselves. [Mr. Wimshurst here assisted Prof. Thompson in experimenting with the machine. Fig. 25 gives in reduced size a photograph of some of the sparks discharged from this most powerful machine.]

My account of influence machines would not be complete if I did not mention a most pregnant little paragraph in Maxwell's "Electricity," wherein that celebrated physicist proposed a form of influence machine (which, so far as I know, has never been made) having a device for avoiding the loss of energy that there necessarily is in the fact of internal sparks occurring in the machine.

Digitized by Google

This he proposed to effect by adding certain supplemental conductors, which entirely obviated, at any rate in theory, the occurrence of internal sparks, and which therefore would add to the efficiency of the machine. Further, my summary of this subject would not be by any means complete (I propose to add it in my printed paper), without reference to the more theoretical researches of Rossetti, of Righi, and of Kohlrausch, and others upon the yield of these machines, and upon their internal resistance. The electromotive force of any given one of these machines is practically constant, no matter what their velocity; but the internal resistance decreases as the velocity increases, once more showing that a moving charge of electricity on a succession of moving charges

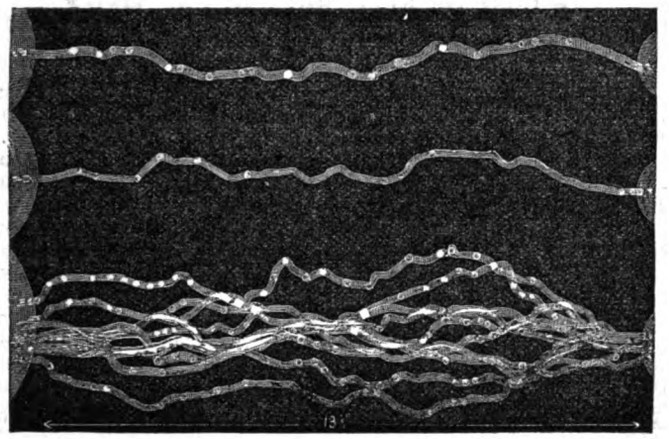

FIG. 25.—Photographs of Sparks from a Wimshurst Machine.

of electricity is the equivalent of a current. This is a topic which one might with advantage pursue a good deal further. There are also some rather interesting researches made by Bouchotte upon a small machine as to the actual work done in the machine in turning it; the torque between the two plates being measured at the same time as the velocity, and so the actual work done in the machine is measured. Time also fails me to tell of the experiments made by Poggendorff, by Holtz himself, and by Christiansen on the reversibility of the functions of the machine, how it can be made to act as a motor, receiving currents from another machine and revolving. Also my account would not be complete if I did not refer to two of the commercial applications of this very interesting scientific instrument. I mean first of all the suggestion of Prof. Lodge that such instruments should be used for collecting dust, smoke, and fog, and in that way dissipating them; and, secondly, the gaslighters which have been made on this very principle. I presume that was not in Nicholson's idea, inasmuch as there was no gas to light in his days. Some years ago Mr. Molison took out a patent for a form of influence-machine, in which he proposed a fixed disc and a movable disc, the movable disc being

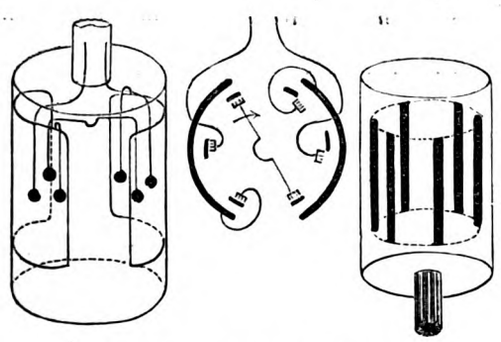

FIG. 26.—Clarke's Gas-lighter.

weighted so that you could swirl it round; but this in the more modern machine has been replaced by a little spring trigger, which actuates a small machine. There is one of them here opened to show how the trigger sets the disc in rotation. Then even before Molison's had come by any means to its present efficient form, Clarke had produced a form of gas lighter with which many of us are familiar (Fig. 26). The internal structure of this is, I may say, almost identical with that of Sir William Thomson's replenisher. There are two tin-foil field-plates, and there is a rotating cylinder of ebonite, which has eight pieces of metal foil upon it to serve as carriers. The essential parts are these two field-plates, the set of carriers on the rotating armature, a pair of neutralising brushes fixed to a cross conductor, and a pair of little appropriating brushes—if you will let me call them so—that take the induced charges as they come over and give them to the field-plates, and give them their accumulated charges. Last of all, there are a pair of discharging wires, connected through the stem of the instrument to the sparking tip, here.

Prof. Thompson exhibited a few other miscellaneous pieces of apparatus, and a discussion followed which will be given in our next week's issue.

(To be concluded.)

PHYSICAL SOCIETY.

At the meeting of this Society, held on the 9th inst., Dr. A. H. FISON described a

"Method of Comparing Very Unequal Capacities."

One of the coatings of each of the condensers to be compared is earth connected, and also connected with one end, A, of a resistance of 20,000 to 30,000 ohms, through which a current is maintained by means of a constant battery. The smaller condenser is charged to the difference of potential existing between the ends A B of the resistance, and is then discharged into the larger one. This operation is repeated a large number of times. The insulated coatings are then joined through a galvanometer, with a point, C, between A and B, C being adjusted so that on completing the galvanometer circuit after n operations there is no deflection.

Let C_1 and C_2 be the capacities of the large and small condenser respectively, R_a and R_b the resistances between C and A, and between C and B respectively, then the ratio of C_2 to C_1 is given by the equation

$$\left(1+\frac{C_2}{C_1}\right)=\frac{R_a}{R_b}.$$

As some time is necessarily occupied by the operations it is impossible to determine in this manner the relation between the instantaneous capacities, and they are therefore compared at a definite time after electrification.

The operations of charging and discharging the small condenser are effected by means of a specially constructed rotating key, which repeats the double operation ten times at each revolution. An automatic arrangement is provided for throwing the key out of action after a pre-determined number of revolutions. The author has used the method for comparing the capacity of a small air condenser with that of an ordinary micro-farad condenser. The capacity of the air condenser was calculated electro-statically, and a calculated correction for the edges was applied. The capacity of the larger was measured electro-magnetically by means of a ballistic galvanometer, and the result of the comparison by the above method gave for b the value $2{\cdot}965\times10^{10}$ centimetres per second, after applying a correction for the capacity of the rotating key.

The author states that under favourable conditions capacities of as high a ratio as 10,000 to 1 can be compared by this method with an error of not more than 0·25 per cent.

Prof. AYRTON pointed out that a similar method had been employed by Prof. Perry and himself, and was described in their Paper on "The Specific Inductive Capacity of Gases." They had, however, abandoned the method on account of the difficulties which they encountered from leakage and absorption. He considered, therefore, that the interest of the Paper consisted in the description of the rotating key, which might very possibly overcome the difficulty due to leakage. In their instrument they had not used any device of the kind. The edge correction would be of interest if it were found that it could be applied with accuracy.

New Electric Lantern.

Mr. LANT CARPENTER exhibited a new form of lantern which had recently been built by Mr. W. C. Hughes, of Dalston. The body, which is made of mahogany, is in the form of a hexagonal prism, and is capable of rotation about a vertical axis.

The adjacent sides are provided respectively with—(1) a lantern microscope, with a very complete set of condensing lenses and objectives, a polariscope, and various adjuncts not often used in connection with lantern microscopes; (2) an ordinary projecting arrangement for lantern slides; (3) an arrangement for the projection of spectra, the prisms being carried on a small table sliding upon rails which also support the projecting lenses. The source of light employed is a modified form of the Brockie-Pell arc lamp.

Prof. S. P. THOMPSON considered that Mr. Carpenter had been judicious in his selection of the Brockie-Pell lamp, which was greatly preferable to the Belfast lamp, which he had himself used for a similar purpose, as in addition to being a focussing lamp, it had the important advantage of having a magnetic governor which was of such a construction as to work equally well when supplied

Digitized by Google

with a constant current or with a current at constant difference of potential.

Prof. A. W. RÜCKER then read a note by Prof. T. E. THORPE and himself on

"Some Additions to the Kew Magnetometer."

In the Kew magnetometer the direction of the geographical meridian is determined by means of a small mirror in which an image of the sun is formed. When using the instrument in the field it is of the utmost importance to have this mirror in perfect adjustment.

The axis is made horizontal by means of a riding level. The plane of the mirror is made parallel to the axis by adjusting it until the image of the cross wires formed in the mirror is unchanged in position when the mirror is inverted in its bearings.

The plane of the mirror is made perpendicular to the axis of the telescope by making the cross wires and their image coincide.

In their recent magnetic survey of Great Britain and Ireland, the authors experienced so much difficulty in making these adjustments in the field that they usually adjusted the mirror from time to time indoors by means of a plumb line, or by observations on some convenient external object.

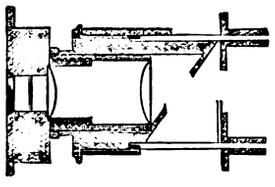

FIG. 1.

In order to eliminate errors of adjustment, the authors always, when possible, took four sets of observations of the sun, reversing the mirror in its bearings, and taking observations both with the observer facing the sun and with his back to it.

On cloudy days the sun frequently does not remain in view long enough to allow these four observations to be taken, and there is often no neighbouring object of sufficient elevation to be used for purposes of correction, and it is then necessary to trust to the previous adjustment. It was found that the mirror was not put out of adjustment to any considerable extent in moving the instrument from place to place; but it was, nevertheless, much more satisfactory to be able to test the adjustment in the field.

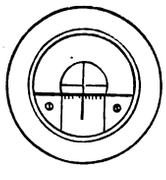

FIG. 2.

The method by the image of the cross wires was difficult to employ on cloudy days, as the light admitted through the aperture in the side of the telescope near the cross wires was insufficient, and even on bright days it was found desirable to envelope the observer's head and the instrument in a dark cloth, which was difficult in a high wind.

To overcome this difficulty the authors have made some additions to the instrument. A polished platinum mirror, with a hole in its centre, is fixed between the eyepiece and the cross wires at an angle of 45deg. with the axis of the telescope as shown in Fig. 1, and by this means when the aperture in the side of the telescope is directed towards a bright portion of the sky a considerable amount of light is reflected on to the cross wires.

To exclude extraneous light a brass tube is fixed between the mirror and the telescope by means of a support fitting into the three holes provided to fix the magnet-box in position. If the background reflects much light a small blackened metal screen, weighted with lead, is placed on the small horizontal circle which carries the mirror, and it can be removed without in any way affecting the adjustment.

It is in some cases impossible to take the back observations, or the sun may be so uncertain that it is desirable to take observations without waiting to adjust the mirror. In order to determine the error introduced the authors place a fine scale engraved on ivory (Fig. 2) in the plane of the cross wires, and determine the angular deviation of the mirror which produces a given displacement in the image of the cross wires on the scale, so that the error of the mirror can be subsequently determined by reading the displacement of the image on the scale. A series of observations taken with the mirror in good and in bad adjustment respectively, the latter being subsequently corrected by this method, were found to give closely concordant results.

The Rev. Father PERRY said that though the authors had described their improvements as small ones, he considered them to be improvements of the greatest value. He had experienced similar difficulties in using the Kew magnetometer, and had frequently found it necessary to use a theodolite instead of the mirror, and it was very inconvenient to be obliged to carry a theodolite in addition to the other instruments.

THE COST OF ELECTRIC ARC LIGHTING.*

BY C. M. KELLER.

It is evident that electricity as an illuminant has entered the lighting field to stay; therefore the cost of its production is of no small import to those who are engaged in the manufacture of gas. In presenting this Paper it is our purpose to show from tests the cost of electric light, in order that all interested may at least be enabled to figure upon it intelligently.

The time is coming when most all street lighting, in the larger cities as well as smaller, will be done by electricity, and it can be furnished by the manufacturers of gas at less cost than any new corporation or by the city itself.

It would be impossible to state the cost of electric light in every locality, as the price of fuel and labour varies as much as in the manufacture of gas, and the increased quantity made decreases the cost of manufacture; for instance, excluding material, the same amount of labour required to make 10,000 cubic feet of gas per day would as readily make 30,000 cubic feet. For like reason the same amount of labour required for a 50-light plant will maintain a 100-light plant. The nearer the machine to its maximum load the less power required per lamp—that is, a 50-light 2,000 candle-power American machine, with one light, requires 20·5 horse-power; the same machine with 25 lights 28·38 horse-power, or 1·13 horse-power per lamp; and with the maximum load, 50 lights, 46·36 horse-power, or ·925 horse-power per lamp.

Many manufacturers of electrical apparatus create a wrong impression in the minds of purchasers by under-estimating the amount of power required to run a dynamo, the power at the machine *only* being taken into consideration and *not* the power of the engine; thus a 50-light machine is rated from 35 to 38 horse-power when it requires 40 to 50 horse-power.

I will state here that the company which I represent has in operation two systems, the Thomson-Houston and the American, a 50-light plant of each, and a separate engine for each machine. After the establishment of a plant the most important thing to be considered is the fuel, which is the cheapest and best adapted for the work to be accomplished. In order to ascertain this, tests were made on October 19th, 20th, and 21st with 79 lamps each night, as follows:—

	No. Lamps.
City circuit all night (12 hours)	49
9:30 o'clock commercial circuit (4½ hours)	18
11 o'clock ,, ,, (6 hours)	12
	79

On the night of the 19th we consumed 6,600lb. of Indiana nut and slack coal at $1.30 per ton, amounting to $4.29; the 20th, 200 cubic feet of tan bark at 50 cents per 100 cubic feet, and 3,200lb. Pittsburg lump coal at $2.50 per ton, amounting to $5.00; the 21st, 4,160lb. Pittsburg coal at $2.50 per ton, amounting to $5.20; from which it will be seen that Indiana nut and slack at the prices named is the cheapest, also that one ton of Pittsburg lump is equal to 1½ ton of Indiana nut and slack coal.

We will now proceed to itemise the actual expenses incurred by an all-night run (12 hours) on a 50lb. Thomson-Houston machine running forty-eight street lights, viz.:—

4,500lb. Ind. nut and slack coal, at $1.30 per ton	$2.93
Engineer, one night, at $50.00 per month	1.67
Trimmer, one day, at $40.00 per month	1.33
Superintendent or electrician, one day, at $50.00 per month	1.66
Waste, &c., one day, at $20.00 per year	05
Water rent, one day, at $40.00 per year	11
96 prs. carbons, at $18.50 per month	1.78
One pint cylinder oil, at 60c. per gallon	07
One quart engine and dynamo oil, at 50c. per gallon	13
One day repairs on machine and lamps,, including globes, at $120.40 per year	33
One day taxes on 50-light plant, assessed at $5,000, at 2¼ per cent.	31
One day interest on 50-light plant ($10,000), at 6 per cent.	1.67
Making a total of	$12.04

* A Paper read before the Western Gas Association of America.

Digitized by Google

Or 2·508 cents per lamp; but since most all street lighting is done by moon calendar, it is necessary to make an estimate of a six-hour run, the average time per night, viz. :—

2,600lb. Ind. nut and slack coal, at $1.30 per ton	$1.69
Engineer, one night, at $50.00 per month	1.67
Superintendent or electrician, one night, at $50.00 per month	1.67
Trimmer, one day, at $40.00 per month	1.33
48 pairs of carbons, at $18 50 per m.	89
Waste, &c., at $20.00 per year	05
Water rent, at $40.00 per year	11
Half-pint cylinder oil, at 60c. per gallon	04
One pint engine and dynamo oil, at 50c. per gallon	05
One day repairs on machine and lamps, including globes, at $120.00 per year	33
One day taxes on 50-light plant, assessed at $5,000, at 2¼ per cent.	31
One day interest on 50 light plant ($10,000), at 6 per cent.	1.67
Making a total of	$9.82

Or 20·45 cents per lamp.

Both of the foregoing tables refer only to street lighting, and any corporation engaging in street lighting alone will find this to be the expense incurred for either all night or moon calendar lighting.

We will now turn our attention to commercial lighting; for this purpose we use a 50-light American machine.

Expense incurred for 48 commercial lights on a six-hour run :—

2,300lb. Ind. nut and slack coal, at $1.30 per ton	$1.50
Engineer and trimmer, one day, at $50.00 per month	1.67
Supt. or electrician, one day, at $50.00 per month	1.67
Waste, &c., one day, at $20.00 per year	05
Water rent, at $40.00 per year	11
48 prs. carbons, at $18.50 per month	89
Half-pint cylinder oil, at 60c. per gallon	04
One pint engine and dynamo oil, at 50c. per gallon	06
Wheeling coal and removing ashes, at $2 per week	29
One day repairs on machine and lamps, including globes, at $63.40 per year	18
One day taxes on 50-light plant assessed at $5,000.00, at 2¼ per cent.	31
One day interest on 50-light plant ($3,000), at 6 per cent.	1.33
Making a total of	$8.10

Or 16·87 cents per lamp.

We have had in our city an average of about 35 commercial lights, and the only difference in maintaining them and the full number (30 lights) is in the amount of fuel and the number of carbons consumed.

These estimates have been made separately, on independent 50-light plants; but combining the two as a 100-light plant, the cost of maintaining 83 lamps on a six-hour run is :—

4,500lb. Ind. nut and slack coal, at $1.30 per ton	$2.93
Engineer, one night, at $50.00 per month	1.67
Supt. or electrician, one night, at $50.00 per month	1.67
Trimmer, one day, at $40.00 per month	1.33
Waste, &c., one day, at $20.00 per year	05
Water rent, one day, at $40.00 per year	11
Wheeling coal and removing ashes, at $2.00 per week	29
83 pairs carbons, at $18.50 per month	1.54
One pint cylinder oil, at 60c. per gallon	07
One quart engine and dynamo oil, at 50c. per gallon	13
One day repairs on machine and lamps, including globes, at $167.95 per year	46
One day taxes on 100-light plant assessed at $8,000, at 2¼ per cent.	50
One day interest on 100 light ($5,000), at 6 per cent.	2.50
Making a total of	13.25

Or 15·96 cents per lamp.

The above is the cost of running forty-eight street lights and thirty-five commercial lights for the first six hours of the night, when it is necessary for us to fire two boilers, which require 1,200lb. of coal to raise steam, or 600lb. for each boiler; now, if the commercial lights were lit in the fore part of the night, as usual, and the street lights not until ten or eleven o'clock, then the firing of one boiler would suffice, thus saving 600lb. of coal in the night run.

In all of the tests it has been shown the amount of Indiana nut and slack coal required per horse-power to be 6½lb., that is, after steam is raised, or with Pittsburg lump coal one-third less, 4·34lb. per horse-power.

It must be borne in mind that nothing has been allowed for depreciation on plant, burning of armatures, repairs on boilers, or accidents of any kind; you will also observe that commercial lighting is more profitable than street lighting, as it requires less labour, the engineer of a 50-light plant performing the duties of a trimmer; also that the circuit is shorter, consequently less resistance and attention.

In reference to the two systems, the Thomson-Houston and the American, no difference in the quantity, quality or steadiness of the light can be detected, as each carry a current of 9·6 amperes, but in regard to the cost of maintaining, there is a vast amount of difference in favour of the American. We have operated the Thomson-Houston system for 15 months to April 1st, 1888; repairs on same for 48 lamps and machine have been $150.50, or $120.40 for one year; making $2.51 per lamp. Three lamps fell accidentally and were broken, repairs on same $21.46, making an additional expense of 44½ cents per lamp.

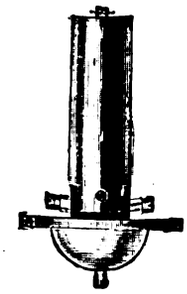
We have operated the American system one year to April 1st, 1888, repairs on same with an average of 35 lamps, $47.55, or $1.36 per lamp, showing a difference of $1.15 per lamp between the two systems, in favour of the American.

We have tested both systems in an impartial manner, by exchanging circuits—that is, by throwing the Thomson-Houston machine on the American circuit, and the American machine on the Thomson-Houston circuit, with fifty and twenty-five lamps; in every instance we find the American system requires the least power, is less expensive in the way of repairs, &c., requires less attention; and these we think are the most important points to be considered.

A gas company can operate a gas and electric plant combined advantageously, as in most cases it requires no purchase of real estate, no additional office rent or clerical force; the salary of the superintendent for the two combined would be less than if operated separately; all steam fitting and pipe work can be done at cost, the coke, breeze, and waste fuel from the gas works can be utilised, and the consumer furnished with either gas or electricity, and thus avoid the necessity of fighting opposing companies with low-priced gas.

BURGLAR ALARM WINDOW AND DOOR CONTACT.

For some time past a reliable burglar alarm contact for the protection of windows and doors has been greatly needed which will not be affected by damp or badly-fitting sashes. The contact illustrated in the adjoining figure is easily fixed in the bottom of the frame; by means of a centre-bit a hole is bored in the sash to fit over the projection, which effectually prevents any water from getting into the contact, and also prevents the possibility of a burglar stopping its action, which he can often do in the usual pattern by



means of a knife. The circuit is completed by means of a washer, making a rubbing contact on two springs. This contact is supplied by Messrs. J. T. Mayfield and Co., of 35A, Queen Victoria-street.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 9th*, 1888.

Our Patent Office has been kept quite busy lately issuing patents relating to electricity, and especially for the utilisation of alternating currents. During the week ended May 29 no fewer than 69 electrical patents were issued, and of these about one half were assigned to the Westinghouse Company by Messrs. H. M. Byllesby, O. B. Shallenberger, P. Lange, and others, who are, I believe, in the service of the company. These patents relate to a number of details, such as circuit-controlling apparatus, indicators, meters, synchronising devices, methods for combining the alternating-current and storage-battery systems, and the like. One patent of seeming novelty is that issued to Mr. C. E. Fritts, whose work in connection with selenium cells two or three years back may not be forgotten by your readers. Mr. Fritts proposes to utilise alternating currents for lighting and power in connection with condensers. The idea of Mr. Fritts seems to be, if one may guess at the meaning of some of the language in the patent, that by the use of condensers he obtains at least three or four times the result from the same current as would be obtained without them. This, of course, would be an enor-

Digitized by Google

mous saving, but, so far, no evidence has been adduced to prove either that the condensers themselves could be given a current capacity equal to the heavy work involved, or that they would operate on a sort of perpetual-motion principle, so that the current which served the lamps in one section of his line would serve half-a-dozen other sections equally as well. Yet another patent which deserves mention is that which has been granted to Camille A. Faure, and assigned by him to the Electrical Accumulator Company. The important claim of this patent is in the method of preparing secondary battery plates, consisting in applying to the plates or supports an active material in the form of a paste prior to immersion in the battery fluid. It has been generally understood that Mr. Brush held a patent of about the same nature, granted to him some three years ago. That being the case, it looks as if there were some contradictory views or actions in the Patent Office to be reconciled.

Speaking of alternating currents reminds me that reports from Boston tell of the active preparations being made for business by the Thomson Welding Company. This company was organised not long ago with strong backing, and is about to put its welding machines on the market. The company has a factory at Lynn, close to the big electric light works of the Thomson-Houston Electric Company. It is said that the welding machines will be sold, but that the company will collect a royalty for all welds that are made. Upon each machine will be placed a meter, which, it is said, will not register unless the weld is complete. There can be no doubt of the practical nature of this latest electrical application, and we shall probably soon hear of the general introduction of this machine.

The cable operators have, for a long time, looked down with a feeling of scorn upon their brothers at the ordinary Morse key, as the working of the latter has been regarded as a very simple matter. But the Morse operator may now hold up his head, for a device has just been brought out in which cable signals are transmitted, practically from an ordinary Morse key. The manner in which this is accomplished has been solved by Mr. P. B. Delany, whose synchronous system of telegraphy is familiar to you by its use in the Postal Telegraph system. As is well known, in the production of signals by the double-key method, many letters require reversed signals and the sending of opposite charges into the cable, thus swinging the syphon alternately above and below the centre line. This alternate charging reduces the speed of the cable, for if a short time only is allowed to elapse between, the outline of the curve does not become clearly defined, and the record flattens out to a straight line. Mr. Delany is working on the plan of transmitting Morse characters by a regularly reversed current of uniform duration. This is accomplished by means of a special construction of the key, together with an automatic device which allows the battery to be in connection with the cable only for a definite time, independent of the period of time during which the key is depressed by the operator. With this arrangement, when the key is depressed it first meets the contact which puts the battery to line, but at the very next instant meets another contact which operates an automatic device that breaks the circuit of the line. Therefore, as long as the key is held down, the negative battery cannot go to line; and hence, if the key be held down for the time represented by a dash, the instrument at the other line will so record it; *i.e.*, in the case of the siphon recorder, the siphon will remain deflected. Now, when the key is raised it makes contact at the back stop, sends the negative current into the cable, and the next instant it makes another contact that again breaks the circuit of the cable. Or, in other words, when the key is pressed down, a current of one polarity is sent; if it is immediately lifted up, a current of positive polarity is sent, lasting for the short time between the downward and upward movement, and forming the dot. If the key be depressed for a continued period the dash is formed; not by the passage of a long impulse of current, but because the positive polarity which terminates each signal has been deferred until the key is lifted up. Thus one current is the beginning of all signals, the other is the ending; the time between the beginning and the end determines whether the signal is a dot or a dash. The record made by this system on a cable one thousand miles long, and having 13,000 ohms resistance and a capacity of 900 microfarads, showed up with the utmost clearness, notwithstanding the fact that one half the number of cells with which the cable is ordinarily worked were available. About a year ago Mr. Delany experimented with this system in England, when on a visit there, and developed a speed of thirty words a minute over an underground cable having 7,000 ohms resistance and 90 microfarads capacity.

Mr. Edison publishes in this month's issue of the *North American Review* a very interesting article on his perfected phonograph. In this article he describes the manner in which the idea of the phonograph first came to him, and in which he worked it out, and he takes occasion to pay his respects rather satirically to those who have during the past ten years undertaken to improve his apparatus by re-inventing it for him, and then claiming it for themselves. The reason why he has let his great invention languish for so long a time is that his system of electric lighting has required all his inventive ability and directive energy, and even yet stands in need of new work in order to keep up with the demands of the times. The article gives an account of the various uses to which the phonograph can be put, and promises a speedy realisation of all of them. Mr. Edison is still working away at some of the details of the instrument, and in the meantime has it in every-day service, all the letters which leave his laboratory being, it is said, phonographically dictated. At any rate, I am told that they bear a little rubber stamp to that effect. I spoke just above about the details of the Edison lighting system. Through imperfections in one of these minor points, a couple of fires have occurred recently in central stations, but I think that hereafter the danger will be avoided. Considerable damage was done last week to one of the stations in Boston by a fire which occurred in one of the equaliser boxes. The station at Fall River suffered not long since in a similar way. These accidents point to the fact that with the stations now loaded up to their full capacity, as so many of them are, the heating of the iron wire in the boxes becomes perilous. Once the evil is known, it will, of course, be remedied, but it took this development and prosperity of the business, loading up the station to their fullest capacity, to expose the source of danger.

A very interesting Paper was read last week before the Boston Electric Club by Mr. G. W. Mansfield of the Thomson-Houston Electric Company, on the subject of elevated railroad systems, and their adaptability to electrical propulsion. In this country, as you are doubtless aware, there are a great many advocates of elevated railroads, of which those in New York may be taken as pre-eminent examples of success and ugliness. The great advantage of elevated roads is, that while they meet the conditions of rapid transit between all parts of the city, they leave the streets below free for ordinary traffic. One of the greatest objections to them is that the use of steam renders them noisy and oftentimes very offensive, and it is believed that a great improvement will be effected by the substitution of electricity for steam. These points were brought out by Mr. Mansfield, who also gave some very interesting details of the various types of elevated railroads, such as where the car could run on two rails on a single support, or straddle a single rail, or hang from a single rail; the last use being exemplified in some degree by the Enos road at South St. Paul, Minn., now being operated with success with Thomson-Houston motors. Mr. Mansfield mentioned that to operate the elevated roads of New York would require 12,000 horse-power of electrical motors, and allowing 50 per cent. loss between the engine and the cars, 24,000 horse-power would be required, which could be divided up along the line in a number of stations with 5,000 horse-power each.

In the June number of the *Street Railway Journal*, Mr. F. J. Sprague has a forcible letter in which he replies, on behalf of the parallel system for street railways, to certain statements which have been made by Mr. S. H. Short, in favour of the series system, in that journal. Mr. Sprague points out the great riskiness of operating the series system, due to the fact that there would be a variable pressure between

Digitized by Google

different machines on a circuit, and from base to base through the earth of from to 100 to 6,000 volts. This, he says, it would be criminal for any public official to allow in use on a street railway, and worse than folly for any street railway man to depend on. As he points out, the case is different from that of the electric light wires, which presumably are well insulated, whereas those for street railway purposes would be perfectly bare, and with such high potentials would be liable to leakage and other trouble at any number of points. Mr. Short, in his article too, had figured out that 10 miles of track with 20 cars on the parallel system would require 2,450 horse-power, and that the daily running expenses would be nearly $250. Against this statement Mr. Sprague sets off the fact that his Richmond road, 12 miles long, with 20 cars each, doing 80 miles daily, requires only 200 horse-power in the station, and that the daily power expenses for operating are only $44.28, or only $1.48 per car. Mr. Short had also intimated that to operate 30 cars on the parallel system was practically impossible. Mr. Sprague replies that in the near future they will have 60 in operation at Richmond. The reply seems fairly conclusive. Mr. Sprague will probably go further, and give exhaustive data on this and on a variety of allied topics, when he reads his Paper before the American Institute of Electrical Engineers on the 19th inst.

The American Bell Telephone Company is now urging its suit against the American Cushman Telephone Company before the United States Court at Chicago for infringement. Cushman, it may be remembered, claims to have been engaged in 1851 in the construction of a Western railroad, and to have put in a little spare time in making a lightning arrester. He laid a telegraph wire from one point of the railroad to another, and enclosed the ends of the wire in plain pine boxes, one of which was put into the cellar of the telegraph station, and from which, much to Mr. Cushman's surprise, came noises like the piping of a bull-frog. He made an investigation, found that he could carry on a conversation over the line, and came to the conclusion that he had made a wonderful discovery. According to his story, he travelled through Ohio in 1867, exhibiting his invention, and he has produced twenty-one witnesses who remember this, and the earlier episode of 1851. The answer of the Bell Telephone Company is that Mr. Cushman had only invented an acoustic telephone, which was not in itself much of a success, and even granting Mr. Cushman all that he claims, his contrivance could not be held to be a prior invention to the Bell telephone and Blake transmitter. Another Western litigation which has just been settled is that of the Brush Company of Cleveland, at Indianapolis, against one of the Jenny companies, as to the infringement of arc lamp patents. The decision has been against the Brush Company, the judge dismissing the bills for want of equity; but it is said that the case will be carried on appeal to the Supreme Court.

NOTES FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

19*th June*, 1888.

I have no change in electrical matters to report since my last letter, and with all the difficulties which the local and Government authorities are placing in the way of those who wish to lay wires for public lighting, it does not seem at all probable that the situation will soon improve. The Minister des Finances, who is at the same time Chief of the Posts and Telegraphs, has obtained from the President of the Republic a new decree for the regulation of electrical installations. It would be too tiresome to give you the full text of this decree, which seems to have been drawn up entirely in the interests of the gas companies. The decree is accompanied by a report of the Minister, who, after having explained the favour which electrical lighting meets from the public, adds:—"However, we cannot refrain from saying that this new industry may give rise to serious accidents if well studied measures of precaution are not imposed upon contractors, in order to control and master, as far as possible, the powerful physical agent which is at work. Accidents, some of which were unhappily followed by loss of life, have already shown the dangers with which, in certain cases, the contact of the human body with conductors carrying powerful currents is accompanied; on the other side, experience proves that electric lighting, justly considered as likey to diminish the risks of fire, may, on the contrary, increase these risks if the fitting up of the wires has not been effected with all the care necessary. This situation, with due regard to the public security, could not be left by the Government," &c. After this preamble, you will have some idea of the nature of the rules which follow the report; they are simply an obstruction to any serious undertaking for the public supply of electricity.

This is for France in general; as regards the City of Paris, there is a new decision of the "Octroi" concerning the duty of coal at its entry in Paris, which if not cancelled, will cause great annoyance to those manufacturers who use the electric light in their works, and will probably stop it entirely. When, some years ago, several of the large manufacturers showed an intention to leave the city of Paris, and establish their works outside, on account of the increase of the Octroi duties, the Municipality, in order to retain them, consented to give them a special license, by which the duty on coal was reduced to about 7 francs per ton. The Administration now says that this reduction cannot be applied to the coal consumed for producing the current for lighting the works, and without taking into consideration the small quantity which is used for this special purpose, they have notified their intention to withdraw the license for the whole. The manufacturers are therefore called upon, either to pay full duty on all the coal they burn, or to stop electric lighting and return to gas in order to preserve their license. It would be difficult to conceive anything more arbitrary and unjust. The Cahier des Charges voted by the Conseil Municipal had already paralysed all serious prospects of the distribution of electricity from central stations for a long while to come, and this new decision of the Octroi will do the rest by preventing the introduction of electric lighting in the manufactories and works of Paris.

In spite of the animosity shown in words by the Conseil Municipal and the Administration against the Parisian Gas Company, it is believed that some important secret reasons exist which induce these bodies to lend their support to the great monopoly of this company.

The shareholders of the Compagnie Continentale Edison had their ordinary meeting on Tuesday last, when a dividend of 35fr. per share was declared. The shares are quoted at 560fr., with dull business. You have already reported the amalgamation of the owners of the Edison and Swan patents in France for incandescent lamps. The new company formed for this purpose takes the name of Compagnie Générale de Lamps à Incandescence, and the registered capital is two millions of francs.

A good deal has recently been said about a new dynamo without brushes, invented by M. Maiche, who up to the present time has chiefly occupied himself with telephony. It is said to give an efficiency of 300 incandescent candles per horse-power. I must, however, confess that in spite of all the efforts I have made I have as yet been unable to see a specimen. I hope soon to be more fortunate, and to be able to send you a description of it.

The Exhibition of 1889 has been, *pour ainsi dire*, inaugurated at the Champs de Mars, by the opening to the public of the Restauration de la Bastille et de la Rue St. Antoine, as they were in 1789. This Exhibition is opened every evening, and lighted electrically by lamps enclosed in lanterns of old style. The lighting of the shops and streets is effected with 900 lamps of 10 candle-power; the gardens are fitted up with 50 Thomson-Houston arc lamps. The plant has been erected by M. Georges Tournier, for the Compagnie Parisienne de l'Air Comprimé.

CORRESPONDENCE.

PARAMAGNETISM AND DIAMAGNETISM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your review of Tyndall's "Researches on Dia-Magnetism" in *The Electrician* of June 8th, p. 146, you remark:—

"There is no doubt that the more recondite problems of magnetism cannot be properly handled without a fuller recognition than is usually made between the *inducing* and *induced* fields. Becquerel's theory ought, probably, to be restated in a form in which it would be shown that the induced field of a paramagnetic body is stronger (or contains more lines per unit area) than the inducing field; while in diamagnetics the induced field is relatively weaker. On this assumption we believe that Prof. Ewing has been able to explain the difference in the direction of rotation of the plane of polarisation without assuming an intrinsic difference in the sign of magnetisation."

There is some mistake here, in the personal reference. We must certainly recognise a distinction between what you term the inducing field ($\mathfrak{H}$) and the induced field ($\mathfrak{B}$), and I am accustomed to regard both of these as having a real existence at any point in a magnetised substance. But I have never suggested that this method of expressing magnetic quality will serve to explain the different rotations of polarised light by paramagnetic and diamagnetic media. And I have always accepted the conclusion which Maxwell has expressed thus: "that the difference between ferromagnetic and diamagnetic substances does not arise merely from the magnetic permeability being in the first case greater, and in the second case less, than that of air, but that the properties of the two classes of bodies are really opposite."—Yours, &c., J. A. EWING.

Dundee, June 11, 1888.

ELECTRICAL OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Dr. Fleming's inquiry in your number of the 8th inst. for the remainder of the current curve up to steady current, I did not take it beyond the firm line in the diagram, because that and other curves indicated the arrival at steady current in about ·05sec., which is confirmed by the action of certain of our apparatus. The increase of current appears to become more uniform after the first perturbation is over.

The successive counter electromotive forces which are set up on the application of the battery appear to diminish in intensity as the electromotive force becomes equally distributed throughout the circuit.

The manner in which the current was measured was by employing an alternate-current commutator driven by an electromotor at uniform speed. One battery was used, a galvanometer being inserted in the circuit between the battery and the commutator, which showed perfectly steady deflections at all the speeds shown in my diagram.

These deflections were reproduced through neutral resistances, which were substituted for the electro-magnets by means of a switch.

The inductive retardation of the galvanometer was unimportant, as it contained only two convolutions of thick wire, and the current was in one direction.

It is well known that the counter electromotive force set up in an electro-magnetic inductive circuit of many turns may be felt as a violent shock, as, for instance, upon the application of a battery to the secondary terminals of an induction coil. The circulation of this discharge of higher potential than the battery and of successively diminishing discharges through the circuit provided by the battery itself may account for the oscillations.

In the case of the cessation of current in such a circuit the number of oscillations per minute may be approximately ascertained by bridging over the terminal wires of a powerful electro-magnet with a telephone; for this purpose it is necessary to short-circuit the electro-magnet just before removing the battery and immediately afterwards, to introduce the telephone without having interrupted the circulation of the induced discharge from the electro-magnet.

This discharge will continue for a length of time dependent on the mass of iron and copper and the degree of magnetisation, and will be heard in the telephone like gentle breathing.

With an electro-magnet like the field-magnets of a dynamo electric machine the discharge will circulate for several seconds.—Yours, &c., F. HIGGINS.

17, Cornhill, E.C., June 21st, 1888.

REPORT BY MESSRS. ALABASTER, GATEHOUSE AND CO., ON THE WEYMERSCH BATTERY.

We have been furnished with the following copy of a report made by Messrs. Alabaster, Gatehouse and Co., to Mr. R. McKenzie, on a new type of the Bunsen cell:—

22, Paternoster-row, E.C., June 15th, 1888.

DEAR SIR: In compliance with the request which you made to us towards the end of last month, that we should conduct a series of

tests with, and report upon, a new depolarising liquid discovered by M. Weymersch, and employed in batteries of the Bunsen type, we beg to submit to you the results of our investigations.

A preliminary trial was made with three square open jars, each having the following internal dimensions :—8¼in. by 8¼in. by 12in. deep.

The quantity of liquid sulphuric acid and water in the proportion of 1 to 20 in each jar was about 16 pints. Immersed in this solution were two 6⅝in. wide zinc plates to the depth of 6½in. Between the zinc plates, and placed in a porous pot 7¼in. by 1½in. by 12in. deep, containing nearly 3¾ pints of the depolarising fluid, was the carbon electrode, of the same linear dimensions as the zincs. These cells were connected in series to an ampere-meter, the current being adjusted by iron wire resistances to 10 amperes or thereabouts, and kept in circuit for 26 hours. The results obtained showed that the battery ran for 26 hours without the current ever falling below 10 amperes, or varying more than 5 per cent., and with a drop of less than 5 per cent. between the maximum and minimum free potential of the cells, whilst an actual rise in the working or available E.M.F. took place. The measured consumption of zinc in the battery, moreover, was only about 8 per cent. above that indicated by theory.

We then decided to employ another battery of 5 cells precisely similar in all respects to the above, and in the table page 220 all the necessary data is furnished.

After keeping the cells on closed circuit for 31½ hours we were compelled, owing to our desire not to leave the battery alone through another night, to put an end to the experiment, although we have not the least doubt that several hours' more work could readily have been obtained before the electrical constants were reduced to the extent of rendering it undesirable to continue the readings. During this lengthened run it will be seen that the free potential of the battery did not vary more than approximately 3 per cent., that the working electromotive force was practically the same at the end of the test as in the beginning, and that the current varied only between 10 and 10·6 amperes.

The actual and theoretical consumption of zinc differ by only 10 per cent., which agrees closely with the data obtained in the preliminary trial, the weighing of the electrodes in the last run having been carried to a greater degree of precision and exactitude, necessitating the employment of grams in balancing-plates of zinc, each weighing nearly 3lb.

The electrical measuring instruments, which had very kindly been loaned to us by Messrs. Sharp and Kent, were independently checked by Mr. H. R. Kempe and Mr. W. M. Mordey. The price per horse-power-hour agrees more closely with the theoretical cost of batteries in which zinc is consumed than that of any other with which we are acquainted, although, of course, the precise figure will largely depend upon the charge per gallon the inventor chooses to make for the depolariser, which we are informed can be manufactured at 6d. per gallon.

We have not hitherto had any battery submitted to us which has given results approaching those above tabulated, and we have no hesitation in expressing the opinion that M. Weymersch has effected a great advance in two-liquid primary batteries.

We may add that the liquids did not appear to rise in temperature during the whole period of the test, a fact which we imagine is unprecedented in batteries of the Bunsen type.

It has long been the aim of inventors to discover a primary battery which should give a high electromotive force, possess a low internal resistance, and give a large and constant current for a considerable period of time with the minimum amount of attention and at the lowest possible cost.

In our opinion M. Weymersch has distanced all competitors n the attempts hitherto made to fulfil the above conditions.—

Yours, &c. H. ALABASTER, GATEHOUSE AND Co.

R. McKenzie, Esq.

ILFRACOMBE LOCAL BOARD AND THE ELECTRIC LIGHT.

At a recent meeting of Ilfracombe Local Board the Surveyor reported that he had received a number of replies to his advertisement in connection with the lighting of the shelter by electricity. Most of the firms wrote to the effect that the affair was so small that, though they would willingly supply the plant, they could not undertake to light the building. The Gülcher Company wrote offering to light the promenade with twelve 300 candle-power incandescent lamps from sunset until 11 p.m., at £360 per year, for a period of not less than three years, after that at £335 per year for a further period of three years, the whole of the plant and work to be provided by the firm, and to be removed by them at the expiration of the term.

Another offer was made by Mr. Woodley, of London, who had that day waited upon the Chairman and surveyor. If the Board would take 200 lamps, and any other party in the town would take 200 additional lamps—each of 50 candle-power—Mr. Woodley would erect and keep them burning on an average for five hours a day. The cost to the town for the 200 lamps (which would be sufficient to light the whole of the town and the shelter) would be £1 a day—£365 a year.

Mr. BAKER : What is the present cost ?

Mr. DAY : Close on £400 a year.

The CLERK announced that the bill for the consumption of gas last year was £423. This was, of course, exclusive of the men's salaries and the cost of lamps.

Mr. GOULD said five hours had been mentioned as a fair average. Mr. Woodley was willing to erect and work the electric light with 200 lamps at the rate of ¼d. per lamp per hour. If they took six hours the cost for the 200 lamps would be 25s. per day.

Mr. RUSSELL said there was no doubt they would be justified in spending that amount.

The SURVEYOR, continuing, said Mr. Woodley's offer was for a year. At the end of the year the Board would have to replace the lamps, and they would cost 4s. per lamp per year.

Mr. DAY : That will be an additional cost of £40 a year after the first year.

It was ultimately agreed to postpone the further considera'ion of the matter for a special meeting.

LEGAL INTELLIGENCE.

Gouraud v. The Edison Gower-Bell Telephone Company of Europe and the Consolidated Telephone Construction and Maintenance Company.

In the Chancery Division, on Tuesday last, Mr. Justice Chitty dismissed with costs an action by Colonel Gouraud, a shareholder in the Edison-Gower-Bell Telephone Company, for an injunction to restrain the two defendant companies from carrying out an arrangement between them with reference to certain patent rights.

Mr. Moulton, Q.C., Mr. Byrne, Q.C., and Mr. Farwell appeared for the plaintiff; Mr. Romer, Q.C., and Mr. Wace, and Mr. Maclean, Q.C., and Mr. Reginald Brown were for the defendants.

COMPANIES' MEETINGS.

LA COMPAGNIE FRANCAISE DU TÉLÉGRAPHE DE PARIS À NEW YORK.

The shareholders of this Company held their annual meeting recently in Paris, M. Brueyre-Dellorier in the chair.

After some remarks from the CHAIRMAN,

M. SORDIER complained of the outpayments which had to be made to foreign companies, which was not the case when there was an understanding with the English companies, and he urged the Company to come back to it. £40,000 was now taken out of their total earnings of £68 000. If the law suit should be lost they would have to pay some 7,000,000fr. or 8,000,000fr., and if they had to pay that and go on paying out £40,000 every year, what would be the end? In twelve years the cable would be worn out. The directors were only instruments of Mackay, and they were his victims. Mackay had made a large fortune, but he was now seeking to make something out of the French shareholders. The directors had been helped in all this by M. Granet.

The CHAIRMAN interposed. He could not allow M. Granet to be attacked. He had been a Minister, and was supported when the English agreement was broken off by M. Peytrail, who considered that what M. Granet had done was quite right.

M. SORDIER said M. Granet had ruined them. He would ask for an indemnity from the Government, who ought to repay the Company for their losses. He proposed to present a petition to the Deputies, which he hoped the other shareholders would sign; if not he would prepare it and send it himself to endeavour to get back their money. He had bought his shares at 150fr. Look at their price to-day!

The CHAIRMAN could not say what their position would be if they lost their lawsuit. They could not re-enter the common purse. It was difficult to suppose they could lose it. The action taken by two Ministers was in conformity with their Articles of Association, and it was difficult to see how the Conseil de Préfecture could upset what had been done. The war of rates had been the cause of all their trouble. He had himself been always against it. They were bound hand and foot, and could not do otherwise than they had done. If they lost their suit they had, perhaps, other means of getting advantages. They might join in the Antilles business, or with the General Telephone Company. When the Antilles scheme came forward some time ago their own shares rose some 50fr. or 60fr. He was asked whether they had power to deal with any of these companies. He could only say they could only do so if they were free from their law suit. Within two months they hoped to have the decision of the Conseil de Préfecture, and they were pushing matters on with all their might. They could do nothing with their legs tied; but as soon as they were free they would be able to swim. They had accomplished a *tour de force* in getting the last judgment; they hoped by another *tour de force* to get a final decision in their favour, and that within three months.

M. DESPECHER said he did not generally take part in these meetings; but he would like to hear some explanation as to what these outpayments were, and to whom they were made—that was, the £40,000 paid to foreign companies.

M. DE BELLEVILLE, in answering, said he must first do full justice to the English companies, who had done their best to facilitate the course of the law suit, and had put no obstacles in the way. The cause of the outpayments was the sums they had to pay to the land lines in America. When they received, say, 30 francs for a message, they had to pay out 45 francs for it, which was 15 francs loss. Again, one word was allowed for an address; but in America they insisted on three being paid for. They had to ask the Government to allow them to refuse messages for the Antilles and South America on account of the outpayments. Since the rupture of the agreement they had met with great hostility from the land lines of America.

M. DESPECHER said as 70 per cent. of the traffic was with New York it did not seem to account for the large total of outpayments. Was any portion of the sum paid to the Commercial Cable Company?

M. BELLEVILLE: Certainly not.

The report was put and adopted, after which the retiring Directors were re-elected and the proceedings closed.

Western Counties and South Wales Telephone Company (Limited).

The third annual meeting of this Company was held at the Royal Hotel, Bristol, on the 7th inst., Mr. Charles Nash presiding.

The MANAGER (Mr. H. F. Lewis) having read the notice convening the meeting,

The CHAIRMAN said that the proposal to increase the company's capital to £500,000, by the creation of new Preference shares, was adjourned for consideration until the 12th of July. He drew the attention of the shareholders to the increased business during the past year, and to the increase which had taken place in the revenue of the Company since 1886—the gross sum now being £23,597, against £15,406 in December, 1886, or an increase of 53 per cent. If they took the subscribers to the various exchanges in 1886, and compared them with the number now, the increase was very satisfactory, the total being 2,044, against 1,318, or at the rate of 54 per cent. The reason why the net result was so good was explained in the report, the wire extensions during the past year being an increase of 977 miles on that of 1886, or no less than 84 per cent. A proportion of that extension was in trunk lines, chiefly in South Wales, where they had a territory which it was desirable to occupy as soon as possible. The cost, however, of extending the trunk wires down to last December had been nearly £19,000, and, so far, the outlay had been unremunerative; but at the same time there had been a demand for the communication, and the Directors felt confident that the current year would bring in a substantial revenue from the trunk system. The total trunk calls now numbered nearly 10,000 a month, as against 5,000 in September, when the system was started, and, generally speaking, the messages had been satisfactorily heard. He had spoken of the importance of occupying the South Wales ground, this being shown by the rapid growth of business from that direction; but, as he had already said, the outlay had been very great. The accounts would have admitted of their paying a small dividend on the Ordinary shares, but the Directors did not think it wise, preferring to carry on the business of the ensuing year by raising the reserve fund to the sum of £1,000. Generally speaking, the business of the Company continued to increase satisfactorily, very few weeks passing without substantial additions being made to the list of subscribers. The report referred to a desire to connect London, Birmingham, and other large towns with their system, and while it was very desirable to do so, still it was a heavy undertaking, and could not be entertained without good promises of support. There was an indirect advantage, the Chairman added, in having trunk lines, for they had the effect of adding

Digitized by Google

materially to the exchange subscribers in the various towns. They were making careful inquiries about connecting the Eddystone Lighthouse with Plymouth and the dockyard, and the Admiralty officials there supported the idea; the Mercantile Marine authorities also looked favourably upon the idea of connecting the lighthouse with the shore, as ships passing up and down Channel could be reported more easily. If the company could see their way to a fair remuneration for their outlay, they might deem it desirable to make the connection. He could not but think it would prove a great advantage to have their coastguard stations, lifeboat stations, and possibly some of their lighthouses connected with their system; and if it was thought desirable these stations should be put in communication with the shore, the telephone system would be by far the best, as it was more easily learnt than the telegraph. Another extension they were looking forward to was the connection of all police stations, and already in Glamorganshire they were making arrangements for connecting the various police stations in that county. There was still, however, room for the further growth of the Company. He moved the adoption of the report.

Mr. MARK WHITWILL seconded the motion. He said that a great deal had been done during the past year by way of preparing for the future. They had been breaking new ground and sowing the seed, and they expected to reap a rich harvest very speedily. People in England, and especially in the West, were only beginning to wake up to the importance of the telephone; but as it was more widely known, its use, he felt confident, would increase month by month. They had evidences of it in the number of fresh connections made during the year.

Mr. RICHARD CORY supported the motion. He said that the telephone was found of great use, and he believed they would in the future find the invention more extensively used than in the past. The Company had a valuable property, and he hoped they would do their best to get other people to adopt the telephone. It was a great convenience to be able to speak with one another in different towns by means of the telephone, and so far as South Wales was concerned their prospects were exceedingly good. Those who had adopted the system were well pleased with it, and they had many others desirous of taking advantage of the convenience offered.

The resolution was then adopted.

On the motion of the CHAIRMAN, a dividend of 6 per cent. to the Preference shareholders was declared.

Mr. J. MORGAN moved, and Mr. BATTEN seconded, the re-election of Messrs. Charles Nash and R. Cory as Directors.

The motion was unanimously carried.

On the motion of Mr. MORGAN, seconded by Mr. CORY, Messrs. Hudson Smith and Co. were appointed to act as auditors, a vote of thanks being accorded to Messrs. Tribe, Clarke and Co., the retiring auditors.

A resolution was adopted to increase the remuneration of the Directors from £300 to £400.

A vote of thanks to the Directors terminated the proceedings.

The Maxim-Weston Electric Company (Limited).

A meeting of shareholders in this Company was held on Friday, the 15th inst., at Cannon-street Hotel, for the purpose of submitting for signature a requisition to be sent to the office calling upon the secretary to summon an extraordinary general meeting for the election of Directors.

Mr. JOHN NEWTON: Gentlemen—This is an informal meeting of shareholders, and in our opinion if Mr. Hugh Watt had attended he would not be entitled to take the Chair. This meeting is entirely free to elect a chairman, and I have much pleasure in proposing that Mr. Greig, the chairman of the last committee, should take the chair.

The motion was seconded and carried unanimously.
